# Contents

Contents.....	3
<b>Chapter 1: Pinout (265) .....</b>	<b>25</b>
The Legend.....	25
Memory bus interface .....	26
Ethernet interface MAC .....	28
General purpose I/O (GPIO) .....	29
System clock.....	41
System clock drawing .....	42
RTC clock and battery backup drawing.....	43
System mode .....	43
System reset .....	45
JTAG Test .....	46
ADC.....	47
POR and battery-backed logic .....	48
Power and ground .....	49
<b>Chapter 2: I/O Control Module .....</b>	<b>51</b>
System memory bus I/O control .....	51
Control and Status registers.....	51
Register address map.....	51
GPIO Configuration registers .....	52
GPIO configuration options .....	53
GPIO Configuration Register #0 .....	53
GPIO Configuration Register #1 .....	54
GPIO Configuration Register #2 .....	55
GPIO Configuration Register #3 .....	55
GPIO Configuration Register #4 .....	56
GPIO Configuration Register #5 .....	56
GPIO Configuration Register #6 .....	57
GPIO Configuration Register #7 .....	57
GPIO Configuration Register #8 .....	58
GPIO Configuration Register #9 .....	58
GPIO Configuration Register #10 .....	59
GPIO Configuration Register #11 .....	59
GPIO Configuration Register #12 .....	60
GPIO Configuration Register #13 .....	60
GPIO Configuration Register #14 .....	61
GPIO Configuration Register #15 .....	61
GPIO Configuration Register #16 .....	62

GPIO Configuration Register #17 .....	62
GPIO Configuration Register #18 .....	63
GPIO Configuration Register #19 .....	63
GPIO Configuration Register #20 .....	64
GPIO Configuration Register #21 .....	64
GPIO Configuration Register #22 .....	65
GPIO Configuration Register #23 .....	65
GPIO Configuration Register #24 .....	66
GPIO Configuration Register #25 .....	66
GPIO Configuration Register #26 .....	67
GPIO Control registers .....	68
GPIO Control Register #0 .....	68
GPIO Control Register #1 .....	69
GPIO Control Register #2 .....	70
GPIO Control Register #3 .....	71
GPIO Status registers.....	72
GPIO Status Register #0.....	72
GPIO Status Register #1.....	73
GPIO Status Register #2.....	74
GPIO Status Register #3.....	75
Memory Bus Configuration register .....	75
 <b>Chapter 3: Working with the CPU .....</b>	<b>79</b>
About the processor .....	79
Arm926EJ-S process block diagram .....	80
Instruction sets .....	80
ARM instruction set .....	80
Thumb instruction set.....	80
Java instruction set .....	81
System control processor (CP15) registers.....	81
ARM926EJ-S system addresses .....	81
Address manipulation example .....	81
Accessing CP15 registers.....	81
Terms and abbreviations .....	82
Register summary.....	83
R0: ID code and cache type status registers .....	84
R0: ID code .....	84
R0: Cache type register.....	84
Cache type register and field description .....	85
Dsize and Isize fields .....	85
R1: Control register .....	86
Control register .....	87
Bit functionality.....	87
ICache and DCache behavior.....	88

R2: Translation Table Base register .....	89
Register format .....	89
R3: Domain Access Control register .....	89
Register format .....	89
Access permissions and instructions .....	89
R4 register .....	90
R5: Fault Status registers .....	90
Access instructions .....	90
Register format .....	90
Register bits .....	90
Status and domain fields .....	91
R6: Fault Address register .....	91
Access instructions .....	91
R7: Cache Operations register .....	92
Write instruction .....	92
Cache functions .....	92
Cache operation functions .....	93
Modified virtual address format (MVA) .....	94
Set/Way format .....	94
Set/Way example .....	94
Test and clean DCache instructions .....	94
Test, clean, and invalidate DCache instruction .....	95
R8: TLB Operations register .....	95
TLB operations .....	95
TLB operation instructions .....	95
Modified virtual address format (MVA) .....	96
R9: Cache Lockdown register .....	96
Cache ways .....	96
Instruction or data lockdown register .....	97
Access instructions .....	97
Modifying the Cache Lockdown register .....	97
Register format .....	97
Cache Lockdown register L bits .....	97
Lockdown cache: Specific loading of addresses into a cache-way .....	98
Cache unlock procedure .....	99
R10: TLB Lockdown register .....	99
Register format .....	99
P bit .....	99
Invalidate operation .....	99
Programming instructions .....	100
Sample code sequence .....	100
R11 and R12 registers .....	100
R13: Process ID register .....	100
FCSE PID register .....	101
Access instructions .....	101

Register format .....	101
Performing a fast context switch .....	101
Context ID register .....	102
Access instructions .....	102
Register format .....	102
R14 register.....	102
R15: Test and debug register .....	102
Jazelle(Java) .....	102
DSP.....	103
Memory Management Unit (MMU) .....	103
MMU Features .....	103
Access permissions and domains .....	104
Translated entries .....	104
MMU program accessible registers .....	105
Address translation .....	105
Translation table base .....	106
TTB register format .....	106
Table walk process .....	107
First-level fetch .....	107
First-level fetch concatenation and address .....	108
First-level descriptor .....	108
Page table descriptors .....	108
First-level descriptor bit assignments: Priority encoding of fault status .....	109
First-level descriptor bit assignments: Interpreting first level descriptor bits [1:0].....	109
Section descriptor .....	109
Section descriptor format .....	109
Section descriptor bit description.....	110
Coarse page table descriptor .....	110
Coarse page table descriptor format .....	110
Coarse page table descriptor bit description.....	110
Fine page table descriptor .....	110
Fine page table descriptor format .....	111
Fine page table descriptor bit description.....	111
Translating section references .....	111
Second-level descriptor.....	112
Second-level descriptor format .....	112
Second-level descriptor pages.....	112
Second-level descriptor bit assignments .....	113
Second-level descriptor least significant bits .....	113
Translation sequence for large page references.....	114
Translating sequence for small page references .....	115
Translation sequence for tiny page references .....	116
Subpages .....	116
MMU faults and CPU aborts .....	117

Alignment fault checking .....	117
Fault Address and Fault Status registers .....	117
Priority encoding table.....	118
Fault Address register (FAR).....	118
FAR values for multi-word transfers .....	118
Compatibility issues .....	119
Domain access control .....	119
Specifying access permissions.....	119
Interpreting access permission bits .....	119
Fault checking sequence.....	120
Alignment faults.....	121
Translation faults .....	122
Domain faults.....	122
Permission faults.....	122
External aborts .....	123
Enabling and disabling the MMU .....	123
Enabling the MMU .....	123
Disabling the MMU .....	124
TLB structure .....	124
Caches and write buffer .....	125
Cache features .....	125
Write buffer.....	126
Enabling the caches .....	126
ICache I and M bit settings .....	127
ICache page table C bit settings.....	127
R1 register C and M bits for DCache .....	127
DCache page table C and B settings .....	127
Cache MVA and Set/Way formats .....	128
Generic, virtually indexed, virtually addressed cache .....	129
ARM926EJ-S cache format .....	130
ARM926EJ-S cache associativity .....	130
Set/way/word format for ARM926EJ-S caches .....	130
Noncacheable instruction fetches .....	131
Self-modifying code .....	131
AHB behavior .....	132
Instruction Memory Barrier .....	132
IMB operation.....	132
Sample IMB sequences .....	133
<b>Chapter 4: System Control Module .....</b>	<b>135</b>
Features .....	135
Bus interconnection .....	135
System bus arbiter .....	135
High speed bus system .....	136

High-speed bus arbiters.....	136
How the bus arbiter works .....	136
Ownership.....	137
Locked bus sequence.....	137
Relinquishing the bus .....	137
SPLIT transfers .....	138
Arbiter configuration example.....	138
Address decoding .....	139
Programmable timers .....	140
Software watchdog timer .....	141
General purpose timers/counters.....	141
Source clock frequency .....	141
GPTC characteristics .....	141
Control field .....	142
16-bit mode options .....	142
Basic PWM function .....	142
Functional block diagram.....	143
Enhanced PWM function .....	143
Sample enhanced PWM waveform .....	144
Quadrature decoder function.....	144
How the quadrature decoder/counter works .....	145
Provides input signals .....	145
Monitors how far the encoder has moved.....	146
Digital filter .....	147
Testing signals.....	147
Timer support .....	147
Interrupt controller .....	147
FIQ interrupts .....	147
IRQ interrupts .....	147
32-vector interrupt controller .....	148
IRQ characteristics .....	148
Interrupt sources .....	148
Vectored interrupt controller (VIC) flow.....	150
Configurable system attributes.....	150
PLL configuration .....	150
PLL configuration and control system block diagram .....	151
Bootstrap initialization .....	151
Configuring the powerup settings.....	151
System configuration registers .....	153
Register address map .....	153
General Arbiter Control register .....	157
BRC0, BRC1, BRC2, and BRC3 registers .....	157
Channel allocation.....	158
AHB Error Detect Status 1 .....	158
AHB Error Detect Status 2 .....	159

AHB Error Monitoring Configuration register .....	160
Timer Master Control register .....	161
Timer 0-4 Control registers.....	163
Timer 5 Control register .....	165
Timer 6-9 Control registers.....	167
Timer 6-9 High registers .....	169
Timer 6-9 Low registers.....	170
Timer 6-9 High and Low Step registers .....	171
Timer 6-9 Reload Step registers .....	171
Timer 0-9 Reload Count and Compare register .....	172
Timer 0-9 Read and Capture register .....	173
Interrupt Vector Address Register Level 31-0 .....	174
Int (Interrupt) Config (Configuration) 31-0 registers .....	174
Individual register mapping .....	174
ISADDR register.....	175
Interrupt Status Active.....	176
Interrupt Status Raw .....	177
Software Watchdog Configuration .....	177
Software Watchdog Timer.....	178
Clock Configuration register .....	179
Module Reset register .....	182
Miscellaneous System Configuration and Status register .....	183
PLL Configuration register.....	185
PLL frequency formula .....	185
Active Interrupt Level ID Status register .....	186
Power Management.....	186
AHB Bus Activity Status .....	189
System Memory Chip Select 0 Dynamic Memory Base and Mask registers.....	190
System Memory Chip Select 1 Dynamic Memory Base and Mask registers.....	190
System Memory Chip Select 2 Dynamic Memory Base and Mask registers.....	191
System Memory Chip Select 3 Dynamic Memory Base and Mask registers.....	192
System Memory Chip Select 0 Static Memory Base and Mask registers .....	193
System Memory Chip Select 1 Static Memory Base and Mask registers .....	194
System Memory Chip Select 2 Static Memory Base and Mask registers .....	195
System Memory Chip Select 3 Static Memory Base and Mask registers .....	196
Gen ID register .....	197
External Interrupt 0-3 Control register.....	198
RTC Module Control register .....	199
 <b>Chapter 5: Memory Controller .....</b>	 <b>201</b>
Features .....	201
Low-power operation.....	202
Low-power SDRAM deep-sleep mode.....	202
Low-power SDRAM partial array refresh.....	202

Memory map .....	202
Power-on reset memory map .....	203
Chip select 1 memory configuration .....	203
Example: Boot from flash, SRAM mapped after boot .....	203
Example: Boot from flash, SDRAM remapped after boot .....	204
Boot from SPI to SDRAM .....	204
Static memory controller .....	205
Write protection .....	206
Extended wait transfers .....	206
Memory mapped peripherals .....	207
Static memory initialization .....	207
Access sequencing and memory width .....	207
Wait state generation .....	208
Programmable enable .....	208
Static memory read control .....	208
Output enable programmable delay .....	209
ROM, SRAM, and Flash .....	209
Static memory read: Timing and parameters .....	209
External memory read transfer with zero wait states .....	209
External memory read transfer with two wait states .....	210
External memory read transfer with two output enable delay states .....	210
External memory read transfers with zero wait states .....	211
Burst of zero wait states with fixed length .....	211
Burst of two wait states with fixed length .....	212
Asynchronous page mode read .....	212
Asynchronous page mode read: Timing and parameters .....	212
External memory page mode read transfer .....	213
External memory 32-bit burst read from 8-bit memory .....	213
Static memory write control .....	214
Write enable programming delay .....	214
SRAM .....	214
Static memory Write: Timing and parameters .....	214
External memory write transfer with zero wait states .....	214
External memory write transfer with two wait states .....	215
External memory write transfer with two write enable delay states .....	215
Two external memory write transfers with zero wait states .....	216
Flash memory .....	216
Bus turnaround .....	217
Bus turnaround: Timing and parameters .....	217
Read followed by write with no turnaround .....	217
Write followed by a read with no turnaround .....	218
Read followed by a write with two turnaround cycles .....	218
Address connectivity .....	219
Address/Data Bus Connectivity .....	219
Byte lane control .....	220

Byte lane configuration in regard to Endianness.....	221
Byte lane configuration for 32-bit peripherals .....	221
Byte lane configuration for 16-bit peripherals .....	221
Byte lane configuration for 8-bit peripherals.....	221
Memory banks constructed from 8-bit or non-byte-partitioned memory devices	
221	
Memory banks constructed from 16-or 32-bit memory devices.....	222
Dynamic memory controller.....	225
Write protection .....	225
Access sequencing and memory width.....	225
SDRAM Initialization .....	225
Left-shift value table: 32-bit wide data bus SDRAM (RBC) .....	226
Left-shift value table: 32-bit wide data bus SDRAM (BRC) .....	227
Left-shift value table: 16-bit wide data bus SDRAM (RBC) .....	227
Left-shift value table: 16-bit wide data bus SDRAM (BRC) .....	228
SDRAM address and data bus interconnect .....	228
32-bit wide configuration.....	228
16-bit wide configuration.....	229
Registers .....	230
Register map.....	230
Reset values .....	232
Control register .....	232
Status register .....	234
Configuration register.....	234
Dynamic Memory Control register .....	235
Dynamic Memory Refresh Timer register .....	236
Register.....	237
Refresh period calculations .....	237
Dynamic Memory Read Configuration register .....	238
Dynamic Memory Precharge Command Period register .....	238
Dynamic Memory Active to Precharge Command Period register .....	239
Dynamic Memory Self-refresh Exit Time register .....	240
Dynamic Memory Last Data Out to Active Time register .....	241
Dynamic Memory Data-in to Active Command Time register .....	241
Dynamic Memory Write Recovery Time register .....	242
Dynamic Memory Active to Active Command Period register.....	243
Dynamic Memory Auto Refresh Period register .....	244
Dynamic Memory Exit Self-refresh register .....	244
Dynamic Memory Active Bank A to Active Bank B Time register .....	245
Dynamic Memory Load Mode register to Active Command Time register .....	246
Static Memory Extended Wait register .....	247
Example .....	248
Dynamic Memory Configuration 0-3 registers .....	248
Address mapping for the Dynamic Memory Configuration registers.....	249
Chip select and memory devices .....	250

Dynamic Memory RAS and CAS Delay 0-3 registers .....	251
StaticMemory Configuration 0-3 registers .....	252
StaticMemory Write Enable Delay 0-3 registers.....	254
Static Memory Output Enable Delay 0-3 registers .....	255
Static Memory Read Delay 0-3 registers .....	256
StaticMemory Page Mode Read Delay 0-3 registers .....	257
Static Memory Write Delay 0-3 registers.....	258
StaticMemory Turn Round Delay 0-3 registers .....	259
 <b>Chapter 6: Ethernet Communication Module .....</b>	<b>261</b>
Features.....	261
Common acronyms .....	261
Ethernet communications module .....	262
Ethernet MAC.....	262
MAC module block diagram .....	263
MAC module features .....	263
PHY interface mappings .....	264
Station address logic (SAL) .....	264
MAC receiver .....	265
Statistics module .....	265
Ethernet front-end module .....	266
Ethernet front-end module (EFE) .....	266
Receive packet processor .....	266
Transmit packet processor .....	267
Receive packet processor .....	267
Power down mode .....	267
Transferring a frame to system memory.....	268
Receive buffer descriptor format .....	268
Receive buffer descriptor format description.....	268
Receive buffer descriptor field definitions .....	269
Transmit packet processor .....	269
Transmit buffer descriptor format.....	270
Transmit buffer descriptor field definitions.....	270
Transmitting a frame.....	271
Frame transmitted successfully .....	272
Frame transmitted unsuccessfully .....	272
Transmitting a frame to the Ethernet MAC.....	272
Ethernet underrun.....	272
Ethernet slave interface.....	273
Interrupts .....	273
Interrupt sources .....	273
Status bits.....	274
Resets .....	274
Multicast address filtering .....	275

Filter entries.....	275
Multicast address filter registers .....	275
Multicast address filtering example 1 .....	275
Multicast address filtering example 2 .....	276
Notes.....	276
Clock synchronization .....	276
Writing to other registers.....	276
Ethernet Control and Status registers .....	277
Register address filter.....	277
Ethernet General Control Register #1 .....	279
Ethernet General Control Register #2 .....	282
Ethernet General Status register .....	283
Ethernet Transmit Status register .....	284
Ethernet Receive Status register .....	286
MAC Configuration Register #1.....	288
MAC Configuration Register #2.....	289
PAD operation table for transmit frames.....	291
Back-to-Back Inter-Packet-Gap register.....	291
Non Back-to-Back Inter-Packet-Gap register .....	292
Collision Window/Retry register.....	293
Maximum Frame register .....	294
MII Management Configuration register .....	295
Clocks field settings .....	296
MII Management Command register.....	296
MII Management Address register .....	297
MII Management Write Data register .....	298
MII Management Read Data register .....	298
MII Management Indicators register .....	299
Station Address registers .....	300
Station Address Filter register .....	301
RegisterHash Tables .....	302
HT1 .....	302
HT2 .....	303
Statistics registers .....	303
Combined transmit and receive statistics counters address map .....	303
Receive statistics counters address map .....	304
Receive byte counter (A060 069C) .....	304
Receive packet counter (A060 06A0) .....	304
Receive FCS error counter (A060 06A4) .....	305
Receive multicast packet counter (A060 06A8) .....	305
Receive broadcast packet counter (A060 06AC) .....	305
Receive control frame packet counter (A060 06B0) .....	305
Receive PAUSE frame packet counter (A060 06B4) .....	305
Receive unknown OP CODE packet counter (A060 06B8) .....	305
Receive alignment error counter (A060 06BC) .....	306

Receive code error counter (A060 06C4) .....	306
Receive carrier sense error counter (A060 06C8) .....	306
Receive undersize packet counter (A060 06CC) .....	306
Receive oversize packet counter (A060 06D0) .....	306
Receive fragments counter (A060 06D4) .....	306
Receive jabber counter (A060 06D8) .....	307
Transmit statistics counters address map .....	307
Transmit byte counter (A060 06E0) .....	307
Transmit packet counter (A060 06E4) .....	308
Transmit multicast packet counter (A060 06E8) .....	308
Transmit broadcast packet counter (A060 06EC) .....	308
Transmit deferral packet counter (A060 06F4) .....	308
Transmit excessive deferral packet counter (A060 06F8) .....	308
Transmit single collision packet counter (A060 06FC) .....	308
Transmit multiple collision packet counter (A060 0700) .....	309
Transmit late collision packet counter (A060 0704) .....	309
Transmit excessive collision packet counter (A060 0708) .....	309
Transmit total collision packet counter (A060 070C) .....	309
Transmit jabber frame counter (A060 0718) .....	309
Transmit FCS error counter (A060 071C) .....	309
Transmit oversize frame counter (A060 0724) .....	310
Transmit undersize frame counter (A060 0728) .....	310
Transmit fragment counter (A060 072C) .....	310
General Statistics registers address map .....	310
Carry Register 1 .....	310
Carry Register 2 .....	311
Carry Register 1 Mask register .....	312
Carry Register 2 Mask register .....	314
RX_A Buffer Descriptor Pointer register .....	315
RX_B Buffer Descriptor Pointer register .....	315
RX_C Buffer Descriptor Pointer register .....	316
RX_D Buffer Descriptor Pointer register .....	316
Ethernet Interrupt Status register .....	317
Ethernet Interrupt Enable register .....	319
TX Buffer Descriptor Pointer register .....	320
Transmit Recover Buffer Descriptor Pointer register .....	321
TX Error Buffer Descriptor Pointer register .....	321
TX Stall Buffer Descriptor Pointer register .....	322
RX_A Buffer Descriptor Pointer Offset register .....	323
RX_B Buffer Descriptor Pointer Offset register .....	324
RX_C Buffer Descriptor Pointer Offset register .....	324
RX_D Buffer Descriptor Pointer Offset register .....	325
Transmit Buffer Descriptor Pointer Offset register .....	325
RX Free Buffer register .....	326
Multicast Address Filter registers .....	327

Multicast Low Address Filter Register #0 .....	327
Multicast Low Address Filter Register #1 .....	327
Multicast Low Address Filter Register #2 .....	327
Multicast Low Address Filter Register #3 .....	327
Multicast Low Address Filter Register #4 .....	327
Multicast Low Address Filter Register #5 .....	327
Multicast Low Address Filter Register #6 .....	328
Multicast Low Address Filter Register #7 .....	328
Multicast High Address Filter Register #0 .....	328
Multicast High Address Filter Register #1 .....	328
Multicast High Address Filter Register #2 .....	328
Multicast High Address Filter Register #3 .....	328
Multicast High Address Filter Register #4 .....	328
Multicast High Address Filter Register #5 .....	328
Multicast High Address Filter Register #6 .....	329
Multicast High Address Filter Register #7 .....	329
Multicast Address Mask registers .....	329
Multicast Low Address Mask Register #0 .....	329
Multicast Low Address Mask Register #1 .....	329
Multicast Low Address Mask Register #2 .....	329
Multicast Low Address Mask Register #3 .....	329
Multicast Low Address Mask Register #4 .....	330
Multicast Low Address Mask Register #5 .....	330
Multicast Low Address Mask Register #6 .....	330
Multicast Low Address Mask Register #7 .....	330
Multicast High Address Mask Register #0 .....	330
Multicast High Address Mask Register #1 .....	330
Multicast High Address Mask Register #2 .....	330
Multicast High Address Mask Register #3 .....	330
Multicast High Address Mask Register #4 .....	330
Multicast High Address Mask Register #5 .....	331
Multicast High Address Mask Register #6 .....	331
Multicast High Address Mask Register #7 .....	331
Multicast Address Filter Enable register .....	331
TX Buffer Descriptor RAM .....	332
Offset+0 .....	332
Offset+4 .....	333
Offset+8 .....	333
Offset+C .....	333
RX FIFO RAM .....	333
Sample hash table code .....	334
 <b>Chapter 7: External DMA .....</b>	<b>339</b>
DMA transfers .....	339

Initiating DMA transfers.....	339
Processor-initiated .....	339
External peripheral-initiated .....	339
DMA buffer descriptor .....	340
DMA buffer descriptor diagram .....	340
Source address [pointer] .....	340
Buffer length .....	340
Destination address [pointer].....	340
Status .....	341
Wrap (W) bit.....	341
Interrupt (I) bit.....	341
Last (L) bit .....	341
Full (F) bit .....	341
Descriptor list processing.....	341
Peripheral DMA read access.....	342
Determining the width of PDEN .....	342
Equation variables .....	342
Peripheral DMA single read access .....	343
Peripheral DMA burst read access.....	343
Peripheral DMA write access.....	343
Determining the width of PDEN .....	344
Peripheral DMA single write access .....	344
Peripheral DMA burst write access.....	344
Peripheral REQ and DONE signaling.....	344
REQ signal.....	344
DONE signal .....	345
Special circumstances.....	345
Static RAM chip select configuration .....	345
Static ram chip select configuration.....	345
Control and Status registers .....	346
Register address map .....	346
DMA Buffer Descriptor Pointer.....	346
DMA Control register .....	347
DMA Status and Interrupt Enable register .....	350
DMA Peripheral Chip Select register .....	352
 <b>Chapter 8: AES Data Encryption/Decryption Module .....</b>	<b>355</b>
Features.....	355
Block diagram .....	356
Data blocks .....	356
AES DMA buffer descriptor .....	356
AES buffer descriptor diagram.....	357
Source address [pointer] .....	357
Source buffer length .....	357

Destination buffer length .....	357
Destination address [pointer] .....	357
AES control .....	357
AES op code .....	358
WRAP (W) bit .....	358
Interrupt (I) bit .....	358
Last (L) bit .....	358
Full (F) bit .....	358
Decryption .....	359
ECB processing .....	359
Processing flow diagram .....	359
CBC, CFB, OFB, and CTR processing .....	360
Processing flow diagram .....	360
CCM mode .....	360
Nonce buffer .....	361
Processing flow .....	361

# Pinout (265)

## C H A P T E R 1

The NS9215 offers a connection to a 10/100 Ethernet network, as well as a glueless connection to SDRAM, PC100 DIMM, flash, EEPROM, and SRAM memories, and an external bus expansion module. It includes four multi-function serial ports, one I2C channel, 12-bit Analog to Digital converter, battery backed real time clock and an AES data encryption/decryption module. The NS215 provides up to 108 general purpose I/O (GPIO) pins and configurable power management with sleep mode.

### The Legend

Heading	Description
Pin	Pin number assigned for a specific I/O signal
Signal	Pin name for each I/O signal. Some signals have multiple function modes and are identified accordingly. The mode is configured through firmware using one or more configuration registers. _n is the signal name indicates that this signal is active is active <i>low</i> .
U/D	U or D indicates whether the pin has an internal pullup resistor or a pulldown resistor: U Pullup (input current source) D Pulldown (input current sink) If no value is listed, that pin has neither an internal pullup nor pulldown resistor.
I/O	The type of signal: input (I), output (O), input/output (I/O), or power (P).
OD (mA)	The output drive of an output buffer. The NS9215 uses one of two drivers: ■ 2 mA ■ 4 mA

## Memory bus interface

Pin	Signal	U/D	I/O	OD	Description
B9	clk_out[0]		O	4	SDRAM bus clock
A15	clk_out[1]		O	4	SDRAM bus clock

B5	cs[3]		O	4	Chip select 3, dy_cs1
B6	cs[2]		O	4	Chip select 2, st_cs1 (Flash boot)
D6	cs[1]		O	4	Chip select 1, dy_cs0 (Boot sdram)
C6	cs[0]		O	4	Chip select 0, st_cs0
C4	ras_n		O	4	SDRAM RAS
A2	cas_n		O	4	SDRAM CAS
C7	we_n		O	4	SDRAM write enable
B3	ap10		O	4	SDRAM A10(AP)
A8	st_oe_n		O	4	Static output enable

- addr [27:24] reset to gpio mode. These address lines cannot be used for boot.
- gpio[31:16] reset to memory data bus data [15:0].

## Ethernet interface MAC

Pin	Signal	U/D	I/O	OD	Description
A12	mdc / gpio[32]	U	I/O	2	MII clock
D11	mdio / gpio[35]	U	I/O	2	MII data
B12	tx_clk / gpio[33]	U	I/O	2	TX clock
A16	txd[3] / gpio[47]	U	I/O	2	TX data 3
D12	txd[2] / gpio[46]	U	I/O	2	TX data 2
C12	txd[1] / gpio[45]	U	I/O	2	TX data 1
B13	txd[0] / gpio[44]	U	I/O	2	TX data 0

Pin	Signal	U/D	I/O	OD	Description
B15	tx_er / gpio[43]	U	I/O	2	TX code err
B14	tx_en / gpio[42]	U	I/O	2	TX enable
C14	col / gpio[48]	U	I/O	2	Collision
C13	crs / gpio[49]	U	I/O	2	Carrier sense
A14	rx_clk / gpio[34]	U	I/O	2	RX clock
E17	rx_d[3] / gpio[41]	U	I/O	2	RX data 3
D16	rx_d[2] / gpio[40]	U	I/O	2	RX data 2
B17	rx_d[1] / gpio[39]	U	I/O	2	RX data 1
D13	rx_d[0] / gpio[38]	U	I/O	2	RX data 0
C17	rx_er / gpio[37]	U	I/O	2	RX error
D17	rx_dv / gpio[36]	U	I/O	2	RX data valid
C11	mii_int/gpio[50] <sup>a</sup>	U	I/O	2	Ethernet MII PHY Int (general purpose)

<sup>a</sup>Ethernet MAC signals reset to gpio mode. If PHY uses MII signals for bootstrap, keep PHY in reset using a spare gpio with a 2K4 pull down resistor, set this port to MII with pull-ups disabled, then set gpio to take PHY out of reset.

## General purpose I/O (GPIO)

- Some signals are multiplexed to two or more GPIOs, to maximize the number of possible applications. These duplicate signals are marked as (*dup*) in the Descriptions column in the table. Selecting the primary GPIO pin and the duplicate GPIO pin for the same function is not recommended. If both the primary GPIO pin and duplicate GPIO pin are programmed for the same function, however, the primary GPIO pin has precedence and will be used.
- The I<sup>2</sup>C module must be held in reset until the GPIO assigned to I<sup>2</sup>C has been configured.

**Note:** All GPIOs except 12 and 16 to 31 are reset to mode 3, input. GPIO 12 is reset to mode 2, reset\_done. GPIO 16 to 31 are reset to mode 0, external memory data 15:0.

Pin	Signal	U/D	I/O	OD	Description

					1 Reserved 1 cs0_oe_n
					2 UART ref clock
					3 gpio_a[3], Endian

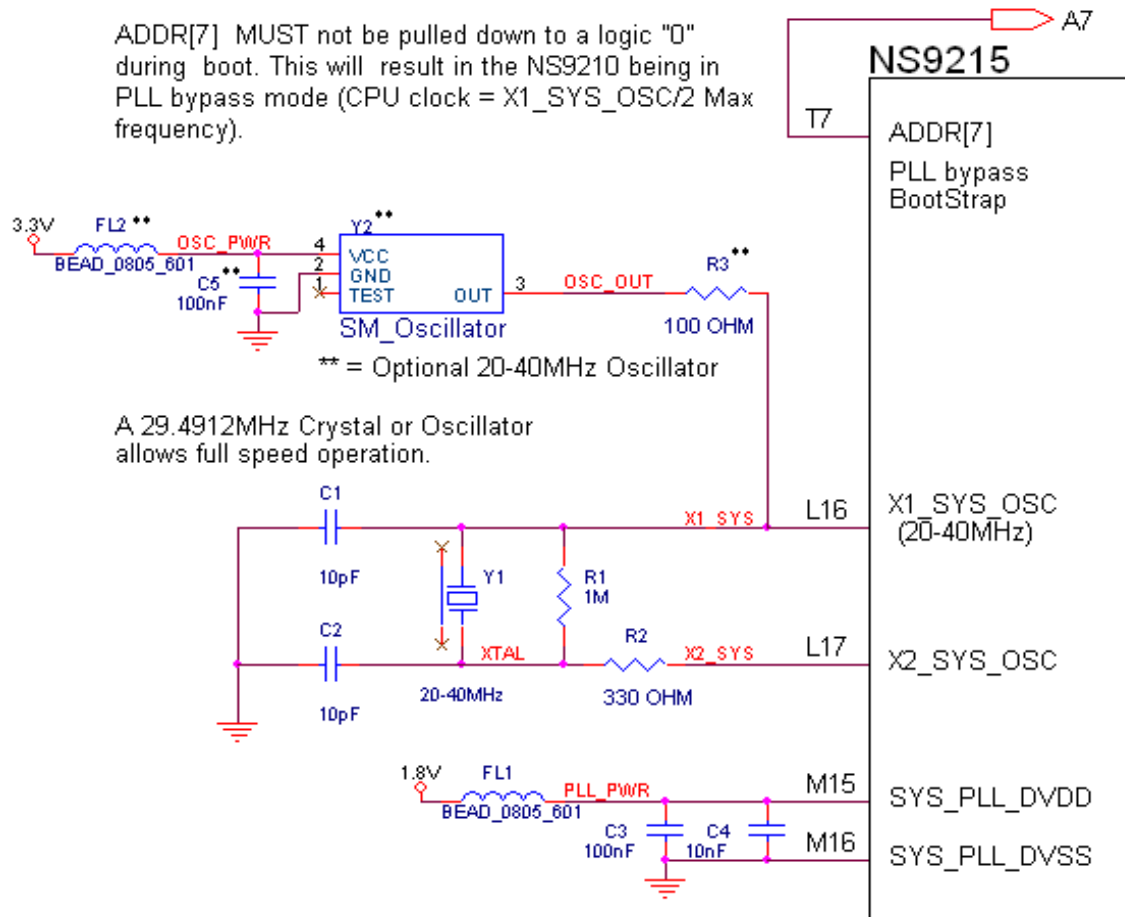

- a. There is a possible conflict when gpio12 is used as the I2C\_SDA signal. In this case the I2C\_SDA signal is driven low while in reset, then driven active high after end of reset, until software configures this pin for the I2C function.

## System clock

Pin	Signal	U/D	I/O	OD	Description
L16	x1_sys_osc		I		System oscillator circuit in
L17	x2_sys_osc		O		System oscillator circuit out
M15	sys_pll_dvdd		P		PLL clean power
M16	sys_pll_dvss		P		PLL clean ground
P2	x1_rtc_osc		I		RTC oscillator circuit in (32.768 KHz)
R2	x2_rtc_osc		O		RTC oscillator circuit out

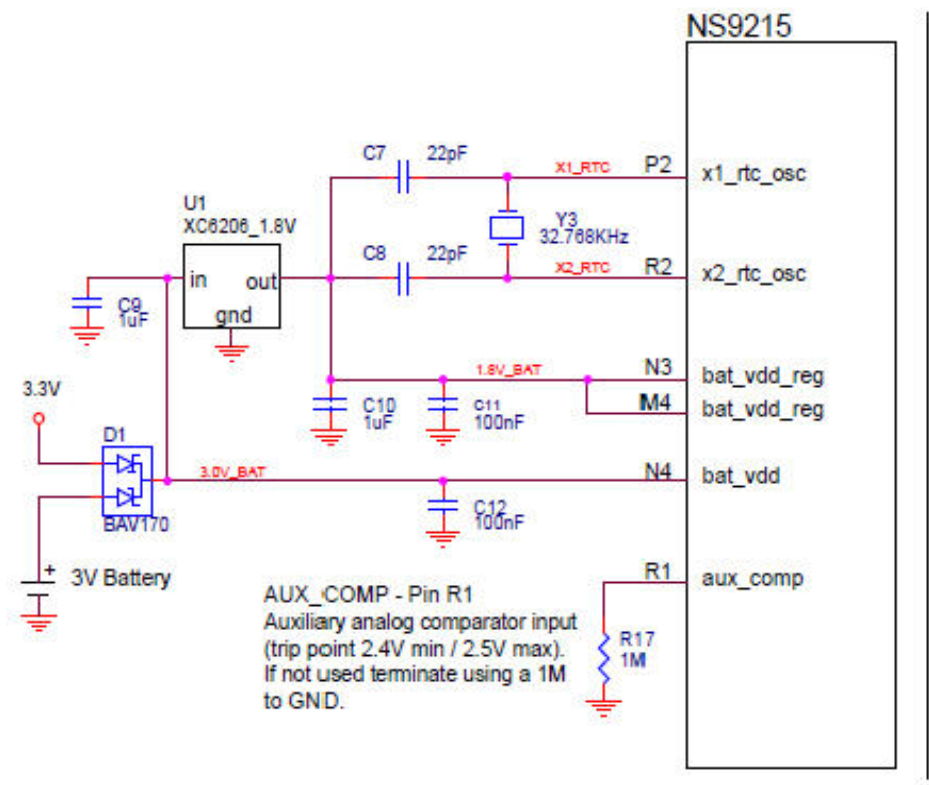

## System clock drawing

RTC clock and battery backup drawing

**Note:** If RTC battery backup is not used, the following connection changes can be made.

N3, M4	bat_vdd_reg	tie to 1.8V
32.788kHz	crystal load capacitors	tie to N3, M4 (1.8V)
N4	bat_vdd	tie to 3.3V
R1	aux_comp	tie to ground

System mode

Pin	Signal	U/D	I/O	OD	Description
M13	sys_mode_2		I		test mode pins
M14	sys_mode_1		I		test mode pins
L14	sys_mode_0		I		test mode pins

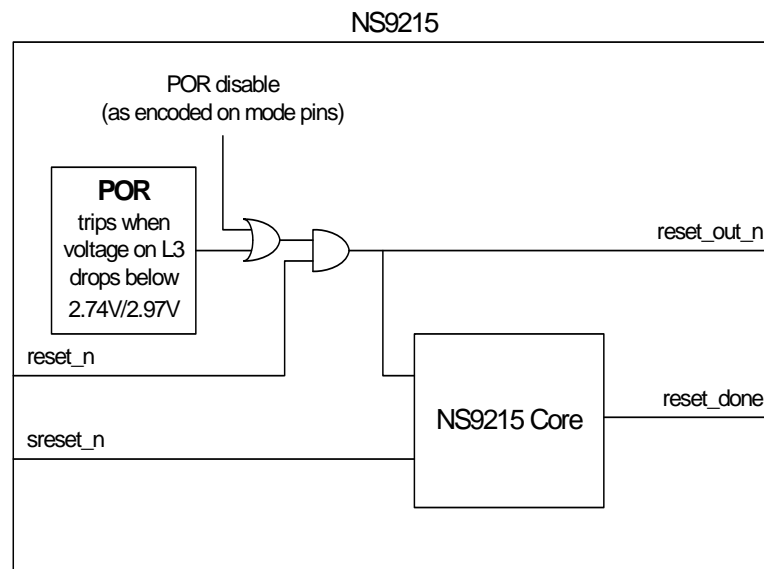

sys_mode_2	sys_mode_1	sys_mode_0	Description
0	0	0	manufacturing test
0	0	1	manufacturing test
0	1	0	manufacturing test
0	1	1	normal operation, boundary scan enabled, POR disabled
1	0	0	normal operation, boundary scan enabled, POR enabled
1	0	1	board test mode, all outputs tristated
1	1	0	normal operation, ARM debug enabled, POR disabled
1	1	1	normal operation, ARM debug enabled, POR enabled

## System reset

Pin	Signal	U/D	I/O	OD	Description
E12	reset_n	U	I		System reset
A5	reset_out_n		O	2	System reset output
A13	reset_done		O	2	Reset done
D9	sreset_n	U	I		Soft system reset

NS9215 internal function	RESET_n pin	SRESET_n pin	PLL Config Reg. Update	Watchdog Time-Out Reset
SPI	YES	YES	YES	YES
BootStrapping PLL	YES	NO	NO	NO
Other Strappings (Endianess)	YES	NO	NO	NO
GPIO Configuration	YES	NO	NO	NO
Other (ASIC) Registers	YES	YES	YES	YES

### Definitions

reset\_n – hardware reset input buffer with pull-up resistor

sreset\_n – soft reset input buffer with pull-up resistor, does not reset the PLL

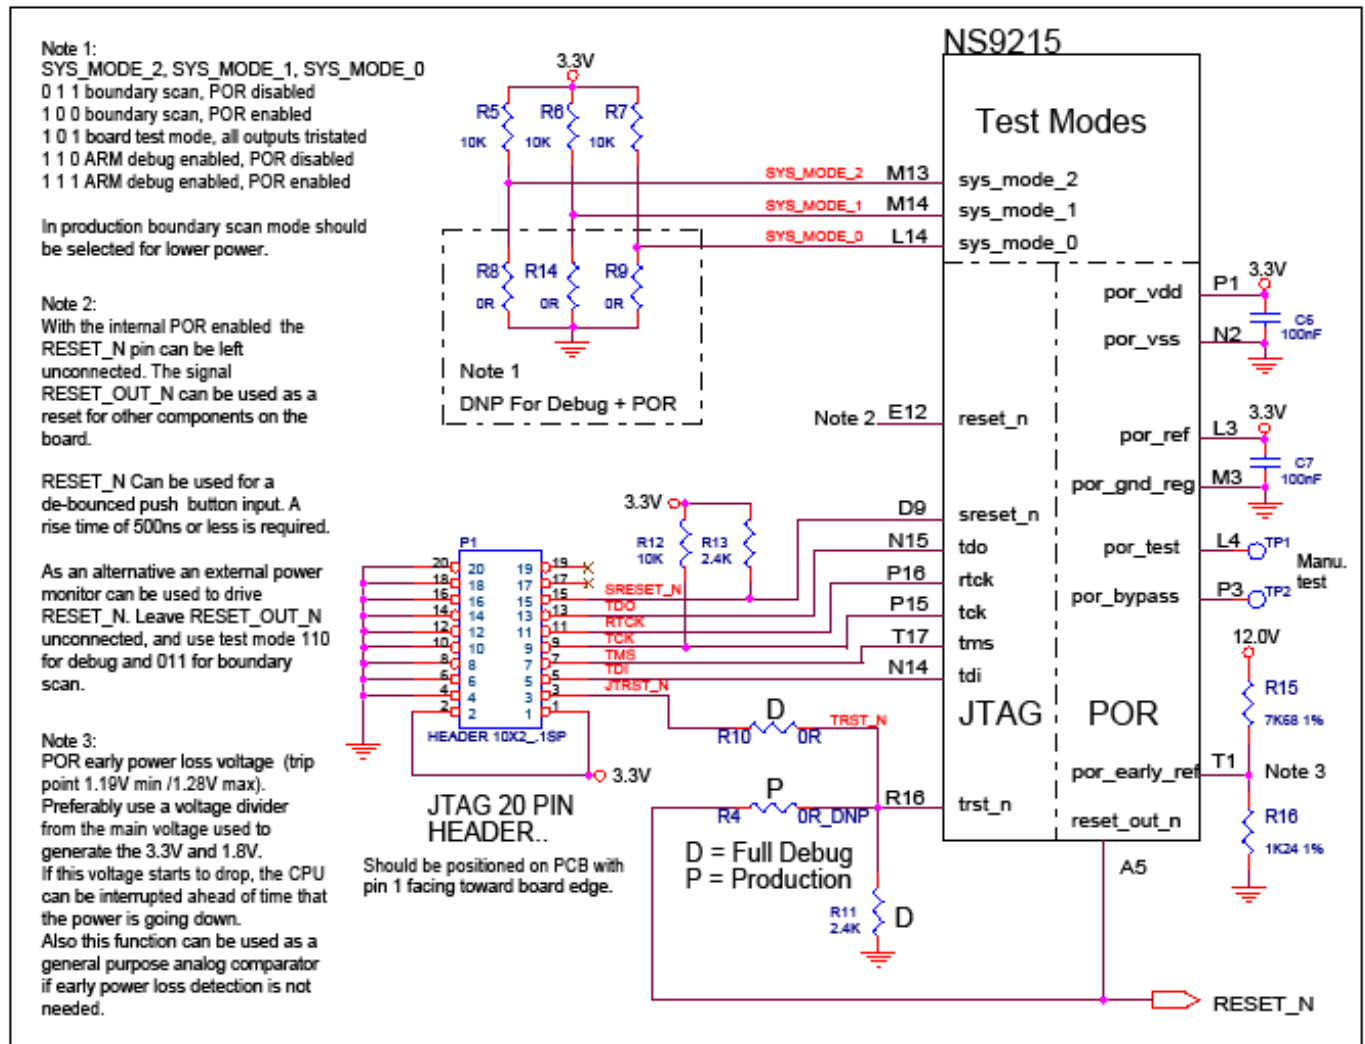

reset\_out\_n – hardware reset to NS9215 core and output buffer, resets all logic in NS9215 core including PLL

reset\_done – reflects the state of the ARM926 reset, for any type of reset event

## JTAG Test

Pin	Signal	U/D	I/O	OD	Description
N14	tdi	U	I		Test data in
N15	tdo		O	2	Test data out
T17	tms	U	I		Test mode select
R16	trst_n	U	I		Test mode reset. For normal operation, this pin is tied to ground or pulled down.
P15	tck		I		Test mode clock
P16	rtck		O	2	Test mode return clock

## ADC

Pin	Signal	U/D	I/O	OD	Description
P4	agnd_ref_adc				Analog reference ground
P5	VREF_adc				Analog reference voltage (3.3max)
T2	vss_adc				ADC_VSS
N6	vdd_adc				ADC VDD (3.3V)
R4	vin0_adc		I		ADC input 0
T3	vin1_adc		I		ADC input 1
R5	vin2_adc		I		ADC input 2
U2	vin3_adc		I		ADC input 3
T4	vin4_adc		I		ADC input 4
U3	vin5_adc		I		ADC input 5
T5	vin6_adc		I		ADC input 6
U4	vin7_adc		I		ADC input 7

If the ADC feature is not used, the inputs must be terminated as shown below:

P4	agnd_ref_adc	tie to ground
P5	VREF_adc	tie to ground
T2	vss_adc	tie to ground
N6	vdd_adc	tie to 3.3V
R4	vin0_adc	tie to ground
T3	vin1_adc	tie to ground
R5	vin2_adc	tie to ground
U2	vin3_adc	tie to ground
T4	vin4_adc	tie to ground
U3	vin5_adc	tie to ground
T5	vin6_adc	tie to ground
U4	vin7_adc	tie to ground

## POR and battery-backed logic

Pin	Signal	U/D	I/O	OD	Description
M3	por_gnd_reg				POR reference ground
N2	por_vss				POR VSS
P1	por_vdd				POR VDD (3.3V)
L3	por_reference				POR reference trip voltage (2.74V min / 2.97V max)
T1	por_early_reference				POR early power loss voltage (1.19V min / 1.28V max)
N4	bat_vdd				Battery VDD (3.0V)
R1	aux_comp				Auxiliary analog comparator input (trip point 2.4V min / 2.5V max)
N3, M4	bat_vdd_reg				Battery regulated core VDD (1.8V)
P3	por_bypass	U	I		POR bypass, pull low to disable POR
L4	por_test				POR analog test pin, leave unconnected

The POR will generate keep reset\_out\_n low between 75ms and 300ms after 3.3V reaches the POR reference trip voltage threshold. The POR reference trip voltage is between 2.74V and 2.97V, with hysteresis between 50mV and 80mV.

If the POR feature is not used, and the RTC is used, the inputs must be terminated as shown below.

M3	por_gnd_reg	tie to ground
N2	por_vss	tie to ground
P1	por_vdd	tie to 3.3V
L3	por_reference	tie to 3.3V
T1	por_early_reference	tie to ground
P3	por_bypass	tie to 1.8V
E12	reset_n	tie to system reset (remains active low 40 ms Min. after 3.3V & 1.8V are valid)
A5	reset_out_n	leave open
M13, M14, L14	sys_mode [2.0]	POR disabled (See System mode table & JTAG drawing following JTAG Test table)

If the RTC feature is not used, the inputs must be terminated as shown below.

N4	Bat_vdd	tie to 3.3V
R1	aux_comp	tie to ground
N3, M4	bat_vdd_reg	tie to ground
P2	x1_rtc_osc	tie to ground
R2	x2_rtc_osc	leave open

If the RTC feature is used, see RTC clock and battery backup drawing on page 43.

# I/O Control Module

## C H A P T E R 2

The NS9215 ASIC contains 108 pins that are designated as general purpose I/O (GPIO).

- The first 16 GPIO can be configured to serve one of five functions.
- The remaining GPIO can be configured to serve one of four functions.

All signals set to a disabled peripheral are held in the inactive state. The I/O control module contains the control register and multiplexing logic required to accomplish this task.

### System memory bus I/O control

The registers in this section control these system memory I/O configuration options:

- System chip select options, used to select which chip select is output
- Upper address option

## Control and Status registers

The I/O control module configuration registers are located at base address 0xA090\_2000.

### Register address map

A090_207C	GPIO Status Register #0	R	Undefined <sup>1</sup>
A090_2080	GPIO Status Register #1	R	Undefined <sup>1</sup>
A090_2084	GPIO Status Register #2	R	Undefined <sup>1</sup>
A090_2088	GPIO Status Register #3	R	Undefined <sup>1</sup>
A090_208C	Memory Bus Configuration register	R/W	007D6344

<sup>1</sup> The reset values for all the status bits are undefined because they depend on the state of the GPIO pins to NS9215.

## GPIO Configuration registers

GPIO Configuration registers #0 through #26 contain the configuration information for each of the 108 GPIO pins. Each GPIO pin can have up to four functions.

Configure each pin for the function and direction needed, using the configuration options shown below.

## GPIO configuration options

Each GPIO configuration section is set up the same way. This table shows the settings using bits D07:00; the same settings apply to the corresponding bits in D15:08, D23:D16, and D31:24.

Bit(s)	Mnemonic	Description
D07:06	Reserved	N/A
D05:03	FUNC	Use these bits to select the function you want to use. For a definition of each function, see “General purpose I/O (GPIO)” on page 29. 000 Function #0 001 Function #1 010 Function #2 011 Function #3 100 Function #4 (applicable only for GPIO 0–15)
D02	DIR	Controls the pin direction when the FUNC field is configured for GPIO mode, function #3. 0 Input 1 Output All GPIO pins reset to the input state. Note: The pin direction is controlled by the selected function in modes #0 through #2.
D01	INV	Controls the inversion function of the GPIO pin. 0 Disables the inversion function 1 Enables the inversion function This bit applies to all functional modes.
D00	PUDIS	Controls the GPIO pin pullup resistor operation. 0 Enables the pullup 1 Disables the pullup Note: The pullup cannot be disabled on GPIO[9], GPIO[12], and on GPIO_A[0] and GPIO_A[1].

## GPIO Configuration Register #0

Address: A090\_2000

## I/O CONTROL MODULE

### GPIO Configuration registers

Bit(s)	Access	Mnemonic	Reset	Description
D31:24	R/W	GPIO3	0x18	GPIO[3] configuration
D23:16	R/W	GPIO2	0x18	GPIO[2] configuration
D15:08	R/W	GPIO1	0x18	GPIO[1] configuration
D07:00	R/W	GPIO0	0x18	GPIO[0] configuration

#### GPIO Configuration Register #1

Address: A090\_2004

Bit(s)	Access	Mnemonic	Reset	Description
D31:24	R/W	GPIO7	0x18	GPIO[7] configuration
D23:16	R/W	GPIO6	0x18	GPIO[6] configuration
D15:08	R/W	GPIO5	0x18	GPIO[5] configuration
D07:00	R/W	GPIO4	0x18	GPIO[4] configuration

## GPIO Configuration Register #2

Address: A090\_2008

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
GPIO11								GPIO10							
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GPIO9								GPIO8							

Bit(s)	Access	Mnemonic	Reset	Description
D31:24	R/W	GPIO11	0x18	GPIO[11] configuration
D23:16	R/W	GPIO10	0x18	GPIO[10] configuration
D15:08	R/W	GPIO9	0x18	GPIO[9] configuration
D07:00	R/W	GPIO8	0x18	GPIO[8] configuration

## GPIO Configuration Register #3

Address: A090\_200C

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
GPIO15								GPIO14

## GPIO Control registers

GPIO Control Registers #0 through #3 contain the control information for each of the 108 GPIO pins. When a GPIO pin is configured as a GPIO output, the corresponding bit in GPIO Control Registers #0 through #3 is driven out the GPIO pin. In all configurations, the CPU has read/write access to these registers.

### GPIO Control Register #0

Address: A090\_206C

Bit(s)	Access	Mnemonic	Reset	Description
D00	R/W	GPIO0	0	GPIO[0] control bit
D01	R/W	GPIO1	0	GPIO[1] control bit
D02	R/W	GPIO2	0	GPIO[2] control bit
D03	R/W	GPIO3	0	GPIO[3] control bit
D04	R/W	GPIO4	0	GPIO[4] control bit
D05	R/W	GPIO5	0	GPIO[5] control bit
D06	R/W	GPIO6	0	GPIO[6] control bit
D07	R/W	GPIO7	0	GPIO[7] control bit
D08	R/W	GPIO8	0	GPIO[8] control bit
D09	R/W	GPIO9	0	GPIO[9] control bit
D10	R/W	GPIO10	0	GPIO[10] control bit
D11	R/W	GPIO11	0	GPIO[11] control bit
D12	R/W	GPIO12	0	GPIO[12] control bit
D13	R/W	GPIO13	0	GPIO[13] control bit
D14	R/W	GPIO14	0	GPIO[14] control bit
D15	R/W	GPIO15	0	GPIO[15] control bit
D16	R/W	GPIO16	0	GPIO[16] control bit
D17	R/W	GPIO17	0	GPIO[17] control bit
D18	R/W	GPIO18	0	GPIO[18] control bit
D19	R/W	GPIO19	0	GPIO[19] control bit
D20	R/W	GPIO20	0	GPIO[20] control bit
D21	R/W	GPIO21	0	GPIO[21] control bit
D22	R/W	GPIO22	0	GPIO[22] control bit
D23	R/W	GPIO23	0	GPIO[23] control bit
D24	R/W	GPIO24	0	GPIO[24] control bit

Bit(s)	Access	Mnemonic	Reset	Description
D25	R/W	GPIO25	0	GPIO[25] control bit
D26	R/W	GPIO26	0	GPIO[26] control bit
D27	R/W	GPIO27	0	GPIO[27] control bit
D28	R/W	GPIO28	0	GPIO[28] control bit
D29	R/W	GPIO29	0	GPIO[29] control bit
D30	R/W	GPIO30	0	GPIO[30] control bit
D31	R/W	GPIO31	0	GPIO[31] control bit

### GPIO Control Register #1

Address: A090\_2070

Bit(s)	Access	Mnemonic	Reset	Description
D00	R/W	GPIO32	0	GPIO[32] control bit
D01	R/W	GPIO33	0	GPIO[33] control bit
D02	R/W	GPIO34	0	GPIO[34] control bit
D03	R/W	GPIO35	0	GPIO[35] control bit
D04	R/W	GPIO36	0	GPIO[36] control bit
D05	R/W	GPIO37	0	GPIO[37] control bit
D06	R/W	GPIO38	0	GPIO[38] control bit
D07	R/W	GPIO39	0	GPIO[39] control bit
D08	R/W	GPIO40	0	GPIO[40] control bit
D09	R/W	GPIO41	0	GPIO[41] control bit
D10	R/W	GPIO42	0	GPIO[42] control bit
D11	R/W	GPIO43	0	GPIO[43] control bit
D12	R/W	GPIO44	0	GPIO[44] control bit
D13	R/W	GPIO45	0	GPIO[45] control bit
D14	R/W	GPIO46	0	GPIO[46] control bit
D15	R/W	GPIO47	0	GPIO[47] control bit
D16	R/W	GPIO48	0	GPIO[48] control bit
D17	R/W	GPIO49	0	GPIO[49] control bit
D18	R/W	GPIO50	0	GPIO[50] control bit
D19	R/W	GPIO51	0	GPIO[51] control bit
D20	R/W	GPIO52	0	GPIO[52] control bit
D21	R/W	GPIO53	0	GPIO[53] control bit

Bit(s)	Access	Mnemonic	Reset	Description
D22	R/W	GPIO54	0	GPIO[54] control bit
D23	R/W	GPIO55	0	GPIO[55] control bit
D24	R/W	GPIO56	0	GPIO[56] control bit
D25	R/W	GPIO57	0	GPIO[57] control bit
D26	R/W	GPIO58	0	GPIO[58] control bit
D27	R/W	GPIO59	0	GPIO[59] control bit
D28	R/W	GPIO60	0	GPIO[60] control bit
D29	R/W	GPIO61	0	GPIO[61] control bit
D30	R/W	GPIO62	0	GPIO[62] control bit
D31	R/W	GPIO63	0	GPIO[63] control bit

### GPIO Control Register #2

Address: A090\_2074

Bit(s)	Access	Mnemonic	Reset	Description
D00	R/W	GPIO64	0	GPIO[64] control bit
D01	R/W	GPIO65	0	GPIO[65] control bit
D02	R/W	GPIO66	0	GPIO[66] control bit
D03	R/W	GPIO67	0	GPIO[67] control bit
D04	R/W	GPIO68	0	GPIO[68] control bit
D05	R/W	GPIO69	0	GPIO[69] control bit
D06	R/W	GPIO70	0	GPIO[70] control bit
D07	R/W	GPIO71	0	GPIO[71] control bit
D08	R/W	GPIO72	0	GPIO[72] control bit
D09	R/W	GPIO73	0	GPIO[73] control bit
D10	R/W	GPIO74	0	GPIO[74] control bit
D11	R/W	GPIO75	0	GPIO[75] control bit
D12	R/W	GPIO76	0	GPIO[76] control bit
D13	R/W	GPIO77	0	GPIO[77] control bit
D14	R/W	GPIO78	0	GPIO[78] control bit
D15	R/W	GPIO79	0	GPIO[79] control bit
D16	R/W	GPIO80	0	GPIO[80] control bit
D17	R/W	GPIO81	0	GPIO[81] control bit
D18	R/W	GPIO82	0	GPIO[82] control bit

Bit(s)	Access	Mnemonic	Reset	Description
D19	R/W	GPIO83	0	GPIO[83] control bit
D20	R/W	GPIO84	0	GPIO[84] control bit
D21	R/W	GPIO85	0	GPIO[85] control bit
D22	R/W	GPIO86	0	GPIO[86] control bit
D23	R/W	GPIO87	0	GPIO[87] control bit
D24	R/W	GPIO88	0	GPIO[88] control bit
D25	R/W	GPIO89	0	GPIO[89] control bit
D26	R/W	GPIO90	0	GPIO[90] control bit
D27	R/W	GPIO91	0	GPIO[91] control bit
D28	R/W	GPIO92	0	GPIO[92] control bit
D29	R/W	GPIO93	0	GPIO[93] control bit
D30	R/W	GPIO94	0	GPIO[94] control bit
D31	R/W	GPIO95	0	GPIO[95] control bit

### GPIO Control Register #3

Address: A090\_2078

Bit(s)	Access	Mnemonic	Reset	Description
D00	R/W	GPIO96	0	GPIO[96] control bit
D01	R/W	GPIO97	0	GPIO[97] control bit
D02	R/W	GPIO98	0	GPIO[98] control bit
D03	R/W	GPIO99	0	GPIO[99] control bit
D04	R/W	GPIO100	0	GPIO[100] control bit
D05	R/W	GPIO101	0	GPIO[101] control bit
D06	R/W	GPIO102	0	GPIO[102] control bit
D07	R/W	GPIO103	0	GPIO[103] control bit
D08	R/W	GPIO_A0	0	GPIO_A[0] control bit
D09	R/W	GPIO_A1	0	GPIO_A[1] control bit
D10	R/W	GPIO_A2	0	GPIO_A[2] control bit

D31:12	N/A	Reserved	N/A	N/A

## GPIO Status registers

GPIO Status Registers #0 through #3 contain the status information for each of the 108 GPIO pins. In all configurations, the value on the GPIO input pin is brought to the status register and the CPU has read-only access to the register.

### GPIO Status Register #0

Address: A090\_207C

Bit(s)	Access	Mnemonic	Reset	Description
D00	R	GPIO0	Undefined	GPIO[0] status bit

# *Working with the CPU*

## C H A P T E R 3

**T**his processor core is based on the ARM926EJ-S processor. The ARM926EJ-S processor belongs to the ARM9 family of general-purpose microprocessors. The ARM926EJ-S processor is targeted at multi-tasking applications in which full memory management, high performance, low die size, and low power are important.

### About the processor

The ARM926EJ-S processor supports the 32-bit ARM and 16-bit Thumb instructions sets, allowing you to trade off between high performance and high code density. The processor includes features for efficient execution of Java byte codes, providing Java performance similar to JIT but without the associated overhead.

The ARM926EJ-S supports the ARM debug architecture, and includes logic to assist in both hardware and software debug. The processor has a Harvard-cached architecture and provides a complete high-performance processor subsystem, including:

- ARM926EJ-S integer core
- Memory Management Unit (MMU) (see "Memory Management Unit (MMU)," beginning on page 103, for information)
- Separate instruction and data AMBA AHB bus interfaces

## Arm926EJ-S process block diagram

This drawing shows the main blocks in the ARM926EJ-S processor.

## Instruction sets

The processor executes three instruction sets:

- 32-bit ARM instruction set
- 16-bit Thumb instruction set
- 8-bit Java instruction set

### ARM instruction set

The ARM instruction set allows a program to achieve maximum performance with the minimum number of instructions. The majority of instructions are executed in a single cycle.

### Thumb instruction set

The Thumb instruction set is simpler than the ARM instruction set, and offers increased code density for code that does not require maximum performance. Code can switch between ARM and Thumb instruction sets on any procedure call.

## Java instruction set

In Java state, the processor core executes a majority of Java bytecodes naturally. Bytecodes are decoded in two states, compared to a single decode stage when in ARM/Thumb mode. See “Jazelle(Java)” on page 102 for more information about Java.

## System control processor (CP15) registers

The system control processor (CP15) registers configure and control most of the options in the ARM926EJ-S processor. Access the CP15 registers using only the MRC and MCR instructions in a privileged mode; the instructions are provided in the explanation of each applicable register. Using other instructions, or MRC and MCR in unprivileged mode, results in an UNDEFINED instruction exception.

## ARM926EJ-S system addresses

The ARM926EJ-S has three distinct types of addresses:

- In the ARM926EJ-S domain: Virtual address (VA)
- In the Cache and MMU domain: Modified virtual address (MVA)
- In the AMBA domain: Physical address (PA)

## Address manipulation example

This is an example of the address manipulation that occurs when the ARM926EJ-S core requests an instruction:

- 1 The ARM926EJ-S core issues the virtual address of the instruction.
- 2 The virtual address is translated using the FCSE PID (fast context switch extension process ID) value to the modified virtual address. The instruction cache (ICache) and memory management unit (MMU) find the modified virtual address (see “R13:Process ID register” on page 100).
- 3 If the protection check carried out by the MMU on the modified virtual address does not abort and the modified virtual address tag is in the ICache, the instruction data is returned to the ARM926EJ-S core.

If the protection check carried out by the MMU on the modified virtual address does not abort but the cache misses (the MVA tag is not in the cache), the MMU translates the modified virtual address to produce the physical address. This address is given to the AMBA bus interface to perform an external access.

## Accessing CP15 registers

Use only MRC and MCR instructions, only in privileged mode, to access CP15 registers. Figure 1 shows the MRC and MCR instruction bit pattern.

**Figure 1: CP15 MRC and MCR bit pattern**

The mnemonics for these instructions are:

MCR{cond} p15,opcode\_1,Rd,CRn,CRm,opcode\_2

MRC{cond} p15,opcode\_1,Rd,CRn,CRm,opcode\_2

If you try to read from a write-only register or write to a read-only register, you will have UNPREDICTABLE results. In all instructions that access CP15:

- The opcode\_1 field SHOULD BE ZERO, except when the values specified are used to select the operations you want. Using other values results in unpredictable behavior.
- The opcode\_2 and CRm fields SHOULD BE ZERO, except when the values specified are used to select the behavior you want. Using other values results in unpredictable behavior.

## Terms and abbreviations

This table lists the terms and abbreviations used in the CP15 registers and explanations.

Term	Abbreviation	Description
UNPREDICTABLE	UNP	<b>For reads:</b> The data returned when reading from this location is unpredictable, and can have any value. <b>For writes:</b> Writing to this location causes unpredictable behavior, or an unpredictable change in device configuration.
UNDEFINED	UND	An instruction that accesses CP15 in the manner indicated takes the UNDEFINED instruction exception.
SHOULD BE ZERO	SBZ	When writing to this field, all bits of the field SHOULD BE ZERO.
SHOULD BE ONE	SBO	When writing to this location, all bits in this field SHOULD BE ONE.
SHOULD BE ZERO or PRESERVED	SBZP	When writing to this location, all bits of this field SHOULD BE ZERO or PRESERVED by writing the same value that has been read previously from the same field.

**Note:** In all cases, reading from or writing any data values to any CP15 registers, including those fields specified as UNPREDICTABLE, SHOULD BE ONE, or SHOULD BE ZERO, does not cause any physical damage to the chip.

## Register summary

CP15 uses 16 registers.

- Register locations 0, 5, and 13 each provide access to more than one register. The register accessed depends on the value of the `opcode_2` field in the CP15 MRC/MCR instructions (see “Accessing CP15 registers” on page 81).
- Register location 9 provides access to more than one register. The register accessed depends on the value of the `CRm` field (see “Accessing CP15 registers” on page 81).

Register	Reads	Writes
0	ID code (based on <code>opcode_2</code> value)	Unpredictable
0	Cache type (based on <code>opcode_2</code> value)	Unpredictable
1	Control	Control
2	Translation table base	Translation table base
3	Domain access control	Domain access control
4	Reserved	Reserved
5	Data fault status (based on <code>opcode_2</code> value)	Data fault status (based on <code>opcode_2</code> value)

7	Cache operations	Cache operations
8	Unpredictable	TLB
9	Cache lockdown (based on <code>CRm</code> value)	Cache lockdown
10	TLB lockdown	TLB lockdown
11 and 12	Reserved	Reserved
13	FCSE PID (based on <code>opcode_2</code> value) FCSE = Fast context switch extension PID = Process identifier	FCSE PID (based on <code>opcode_2</code> value) FCSE = Fast context switch extension PID = Process identifier
13	Context ID (based on <code>opcode_2</code> value)	Context ID (based on <code>opcode_2</code> value)
14	Reserved	Reserved
15	Test configuration	Test configuration

All CP15 register bits that are defined and contain state are set to 0 by reset, with these exceptions:

- The V bit is set to 0 at reset if the `VINITHI` signal is low, and set to 1 if the `VINITHI` signal is high.

- The B bit is set to 0 at reset if the BIGENDINIT signal is low, and set to 1 if the BIGENDINIT signal is high.

R0: ID code and cache type status registers

Register R0 access the ID register, and cache type register. Reading from R0 returns the device ID, and the cache type, depending on the `opcode_2` value:

<code>opcode_2=0</code>	ID value
<code>opcode_2=1</code>	instruction and data cache type

The `CRm` field SHOULD BE ZERO when reading from these registers. This table shows the instructions you can use to read register R0.

Function	Instruction
Read ID code	<code>MRC p15,0,Rd,c0,c0,{0, 3-7}</code>
Read cache type	<code>MRC p15,0,Rd,c0,c0,1</code>

Writing to register R0 is UNPREDICTABLE.

R0: ID code

R0: ID code is a read-only register that returns the 32-bit device ID code. You can access the ID code register by reading CP15 register R0 with the `opcode_2` field set to any value other than 1 or 2. Note this example:

`MRC p15, 0, Rd, c0, c0, {0, 3-7};` returns ID

This is the contents of the ID code register.

Bits	Function	Value
[31:24]	ASCII code of implementer trademark	0x41
[23:20]	Specification revision	0x0
[19:16]	Architecture (ARMv5TEJ)	0x6
[15:4]	Part number	0x926
[3:0]	Layout revision	0x0

R0: Cache type register

R0: Cache type is a read-only register that contains information about the size and architecture of the instruction cache (ICache) and data cache (DCache) enabling operating systems to establish how to perform operations such as cache cleaning and lockdown. See “Cache features” on page 125 for more information about cache.

You can access the cache type register by reading CP15 register R0 with the opcode\_2 field set to 1. Note this example:

MRC p15, 0, Rd, c0, c0, 1; returns cache details

### Cache type register and field description

31			28			25			24			23			12																							
0			0			0			Ctype			S			Dsize												Isize											

Field	Description
Ctype	Determines the cache type, and specifies whether the cache supports lockdown and how it is cleaned. Ctype encoding is shown below; all unused values are reserved. Value: 0b1110 Method: Writeback Cache cleaning: Register 7 operations (see “R7:Cache Operations register” on page 92) Cache lockdown: Format C (see “R9: Cache Lockdown register” on page 96)
S bit	Specifies whether the cache is a unified cache (S=0) or separate ICache and DCache (S=1). Will always report separate ICache and DCache for this processor.
Dsize	Specifies the size, line length, and associativity of the DCache.
Isize	Species the size, length and associativity of the ICache.

### Dsize and Isize fields

The Dsize and Isize fields in the cache type register have the same format, as shown:

11	10	9	6	5	3	2	1	0
0	0	Size	Assoc	M	Len			

The field contains these bits:

Field	Description						
Size	<p>Determines the cache size in conjunction with the M bit.</p> <ul style="list-style-type: none"> <li>■ The M bit is 0 for DCache and ICache.</li> <li>■ The size field is bits [21:18] for the DCache and bits [9:6] for the ICache.</li> <li>■ The minimum size of each cache is 4 KB; the maximum size is 128 KB.</li> <li>■ Cache size encoding with M=0:</li> </ul> <table> <tr> <th>Size field</th><th>Cache size</th></tr> <tr> <td>0b0011</td><td>4 KB</td></tr> <tr> <td>0b0100</td><td>8 KB</td></tr> </table> <p>Note: The processor always reports 4KB for DCache and 8KB for ICache.</p>	Size field	Cache size	0b0011	4 KB	0b0100	8 KB
Size field	Cache size						
0b0011	4 KB						
0b0100	8 KB						
Assoc	<p>Determines the cache associativity in conjunction with the M bit.</p> <ul style="list-style-type: none"> <li>■ The M bit is 0 for both DCache and ICache.</li> <li>■ The assoc field is bits [17:15] for the DCache and bits [5:3] for the ICache.</li> <li>■ Cache associativity with encoding:</li> </ul> <table> <tr> <th>Assoc field</th><th>Associativity</th></tr> <tr> <td>0b010</td><td>4-way</td></tr> <tr> <td>Other values</td><td>Reserved</td></tr> </table>	Assoc field	Associativity	0b010	4-way	Other values	Reserved
Assoc field	Associativity						
0b010	4-way						
Other values	Reserved						
M bit	<p>Multiplier bit. Determines the cache size and cache associativity values in conjunction with the size and assoc fields.</p> <p>Note: This field must be set to 0 for the ARM926EJ-S processor.</p>						
Len	<p>Determines the line length of the cache.</p> <ul style="list-style-type: none"> <li>■ The len field is bits [13:12] for the DCache and bits [1:0] for the ICache.</li> <li>■ Line length encoding:</li> </ul> <table> <tr> <th>Len field</th><th>Cache line length</th></tr> <tr> <td>10</td><td>8 words (32 bytes)</td></tr> <tr> <td>Other values</td><td>Reserved</td></tr> </table>	Len field	Cache line length	10	8 words (32 bytes)	Other values	Reserved
Len field	Cache line length						
10	8 words (32 bytes)						
Other values	Reserved						

## R1: Control register

Register R1 is the control register for the ARM926EJ-S processor. This register specifies the configuration used to enable and disable the caches and MMU (memory management unit). It is recommended that you access this register using a read-modify-write sequence.

For both reading and writing, the CRm and opcode\_2 fields SHOULD BE ZERO. Use these instructions to read and write this register:

MRC p15, 0, Rd, c1, c0, 0; read control register

MCR p15, Rd, c1, c0, 0; write control register

All defined control bits are set to zero on reset except the V bit and B bit.

- The V bit is set to zero at reset if the VINITHI signal is low.
- The B bit is set to zero at reset if the BIGENDINIT signal is low, and set to one if the BIGENDINIT signal is high.

## Control register

## Bit functionality

Bits	Name	Function
[31:19]	N/A	Reserved: <ul style="list-style-type: none"> <li>When read, returns an UNPREDICTABLE value.</li> <li>When written, SHOULD BE ZERO, or a value read from bits [31:19] on the same processor.</li> <li>Use a read-modify-write sequence when modifying this register to provide the greatest future compatibility.</li> </ul>
[18]	N/A	Reserved, SBO. Read = 1, write = 1.
[17]	N/A	Reserved, SBZ. read = 0, write = 0.
[16]	N/A	Reserved, SBO. Read = 1, write = 1.
[15]	L4	Determines whether the T is set when load instructions change the PC. <ul style="list-style-type: none"> <li>0 Loads to PC set the T bit</li> <li>1 Loads to PC do not set the T bit</li> </ul>
[14]	RR bit	<b>Replacement strategy for ICache and DCache</b> <ul style="list-style-type: none"> <li>0 Random replacement</li> <li>1 Round-robin replacement</li> </ul>
[13]	V bit	<b>Location of exception vectors</b> <ul style="list-style-type: none"> <li>0 Normal exception vectors selected; address range=0x0000 0000 to 0x0000 001C</li> <li>1 High exception vectors selected; address range=0xFFFF 0000 to 0xFFFF 001C</li> </ul> Set to the value of VINITHI on reset.
[12]	I bit	<b>ICache enable/disable</b> <ul style="list-style-type: none"> <li>0 ICache disabled</li> <li>1 ICache enabled</li> </ul>
[11:10]	N/A	SHOULD BE ZERO
[9]	R bit	<b>ROM protection</b> Modifies the ROM protection system.
[8]	S bit	<b>System protection</b> Modifies the MMU protection system. See "Memory Management Unit (MMU)," beginning on page 103.
[7]	B bit	Endianness <ul style="list-style-type: none"> <li>0 Little endian operation</li> <li>1 Big endian operation</li> </ul> Set to the value of BIGENDINIT on reset.

Bits	Name	Function
[6:3]	N/A	Reserved. SHOULD BE ONE.
[2]	C bit	<b>DCache enable/disable</b> 0 Cache disabled 1 Cache enabled
[1]	A bit	<b>Alignment fault enable/disable</b> 0 Data address alignment fault checking disabled 1 Data address alignment fault checking enabled
[0]	M bit	<b>MMU enable/disable</b> 0 Disabled 1 Enabled

### ICache and DCache behavior

The M, C, I, and RR bits directly affect ICache and DCache behavior, as shown:

Cache	MMU	Behavior
ICache disabled	Enabled or disabled	All instruction fetches are from external memory (AHB).
ICache enabled	Disabled	All instruction fetches are cachable, with no protection checking. All addresses are flat-mapped; that is: VA=MVA=PA.
ICache enabled	Enabled	Instruction fetches are cachable or noncachable, and protection checks are performed. All addresses are remapped from VA to PA, depending on the MMU page table entry; that is, VA translated to MVA, MVA remapped to PA.
DCache disabled	Enabled or disabled	All data accesses are to external memory (AHB).
DCache enabled	Disabled	All data accesses are noncachable nonbufferable. All addresses are flat-mapped; that is, VA=MVA=PA.
DCache enabled	Enabled	All data accesses are cachable or noncachable, and protection checks are performed. All addresses are remapped from VA to PA, depending on the MMU page table entry; that is, VA translated to MVA, MVA remapped to PA.

If either the DCache or ICache is disabled, the contents of that cache are not accessed. If the cache subsequently is re-enabled, the contents will not have changed. To guarantee that memory coherency is maintained, the DCache must be cleaned of dirty data before it is disabled.

## R2: Translation Table Base register

Register R2 is the Translation Table Base register (TTBR), for the base address of the first-level translation table.

- Reading from R2 returns the pointer to the currently active first-level translation table in bits [31:14] and an UNPREDICTABLE value in bits [13:0].
- Writing to R2 updates the pointer to the first-level translation table from the value in bits[31:14] of the written value. Bits [13:0] SHOULD BE ZERO.

Use these instructions to access the Translation Table Base register:

MRC p15, 0, Rd, c2, c0, 0; read TTBR

MCR p15, 0, Rd, c2, c0, 0; write TTBR

The CRm and opcode\_2 fields SHOULD BE ZERO when writing to R2.

### Register format

## R3: Domain Access Control register

Register R3 is the Domain Access Control register and consists of 16 two-bit fields.

- Reading from R3 returns the value of the Domain Access Control register.
- Writing to R3 writes the value of the Domain Access Control register.

### Register format

### Access permissions and instructions

Each two-bit field defines the access permissions for one of the 16 domains (D15-D0):

- 00 No access: Any access generates a domain fault
- 01 Client: Accesses are checked against the access permission bits in the section or page descriptor
- 10 Reserved: Currently behaves like no access mode (00)
- 11 Manager: Accesses are not checked against the access permission bits, so a permission fault cannot be generated.

Use these instructions to access the Domain Access Control register:

MRC p15, 0, Rd, c3, c0, 0; read domain access permissions

MCR p15, 0, Rd, c3, c0, 0; write domain access permissions

## R4 register

Accessing (reading or writing) this register causes UNPREDICTABLE behavior.

## R5: Fault Status registers

Register R5 accesses the Fault Status registers (FSRs). The Fault Status registers contain the source of the last instruction or data fault. The instruction-side FSR is intended for debug purposes only.

The FSR is updated for alignment faults and for external aborts that occur while the MMU is disabled. The FSR accessed is determined by the `opcode_2` value:

<code>opcode_2=0</code>	Data Fault Status register (DFSR)
<code>opcode_2=1</code>	Instruction Fault Status register (IFSR)

See "Memory Management Unit (MMU)," beginning on page 103, for the fault type encoding.

### Access instructions

Access the FSRs using these instructions:

```
MRC p15, 0, Rd, c5, c0, 0; read DFSR
MCR p15, 0, Rd, c5, c0, 0; write DFSR
MRC p15, 0, Rd, c5, c0, 1; read IFSR
MCR p15, 0, Rd, c5, c0, 1; write IFSR
```

### Register format

31	9	8	7	4	3	0
UNP/SBZ						
0						
Domain				Status		

### Register bits

Bits	Description
[31:9]	UNPREDICTABLE/SHOULD BE ZERO
[8]	Always reads as zero. Writes are ignored.
[7:4]	Specifies which of the 16 domains (D15–D0) was being accessed when a data fault occurred.
[3:0]	Type of fault generated. (See "Memory Management Unit (MMU)," beginning on page 103.)

**Status and domain fields**

This table shows the encodings used for the status field in the Fault Status register, and indicates whether the domain field contains valid information. See “MMU faults and CPU aborts” on page 117 for information about MMU aborts in Fault Address and Fault Status registers.

Priority	Source	Size	Status	Domain
Highest	Alignment	N/A	0b00x1	Invalid
	External abort on translation	First level	0b1100	Invalid
		Second level	0b1110	Valid
	Translation	Section page	0b0101	Invalid
			0b0111	Valid
	Domain	Section page	0b1001	Valid
			0b1011	Valid
	Permission	Section page	0b1101	Valid
			0b1111	Valid
Lowest	External abort	Section page	0b1000	Valid
			0b1010	Valid

**R6: Fault Address register**

Register R6 accesses the Fault Address register (FAR). The Fault Address register contains the modified virtual address of the access attempted when a data abort occurred. This register is updated only for data aborts, not for prefetch aborts; it is updated also for alignment faults and external aborts that occur while the MMU is disabled.

Writing R6 sets the Fault Address register to the value of the data written. This is useful for debugging, to restore the value of a Fault Address register to a previous state.

The CRm and opcode\_2 fields SHOULD BE ZERO when reading or writing R6.

**Access instructions**

Use these instructions to access the Fault Address register:

```
MRC p15, 0, Rd, c6, c0, 0; read FAR
MCR p15, 0, Rd, c6, c0, 0; write FAR
```

## R7:Cache Operations register

Register R7 controls the caches and write buffer. The function of each cache operation is selected by the `opcode_2` and `CRm` fields in the MCR instruction that writes to CP15 R7. Writing other `opcode_2` or `CRm` values is UNPREDICTABLE.

Reading from R7 is UNPREDICTABLE, with the exception of the two test and clean operations (see “Cache operation functions” on page 93 and “Test and clean DCache instructions” on page 94).

### Write instruction

Use this instruction to write to the Cache Operations register:

MCR p15, `opcode_1`, Rd, CRn, CRm, `opcode_2`

### Cache functions

This table describes the cache functions provided by register R7.

Function	Description
Invalidate cache	Invalidates all cache data, including any dirty data.
Invalidate single entry using either index or modified virtual address	Invalidates a single cache line, discarding any dirty data.
Clean single data entry using either index or modified virtual address	Writes the specified DCache line to main memory if the line is marked valid and dirty. The line is marked as not dirty, and the valid bit is unchanged.
Clean and invalidate single data entry using wither index or modified virtual address.	Writes the specified DCache line to main memory if the line is marked valid and dirty. The line is marked not valid.
Test and clean DCache	Tests a number of cache lines, and cleans one of them if any are dirty. Returns the overall dirty state of the cache in bit 30. (See “Test and clean DCache instructions” on page 94).
Test, clean, and invalidate DCache	Tests a number of cache lines, and cleans one of them if any are dirty. When the entire cache has been tested and cleaned, it is invalidated. (See “Test and clean DCache instructions” on page 94).
Prefetch ICache line	Performs an ICache lookup of the specified modified virtual address. If the cache misses and the region is cachable, a linefill is performed.

Function	Description
Drain write buffer	<p>Acts as an explicit memory barrier. This instruction drains the contents of the write buffers of all memory stores occurring in program order before the instruction is completed. No instructions occurring in program order after this instruction are executed until the instruction completes.</p> <p>Use this instruction when timing of specific stores to the level two memory system has to be controlled (for example, when a store to an interrupt acknowledge location has to complete before interrupts are enabled).</p>
Wait for interrupt	<p>Drains the contents of the write buffers, puts the processor into low-power state, and stops the processor from executing further instructions until an interrupt (or debug request) occurs. When an interrupt does occur, the MCR instruction completes, and the IRQ or FIRQ handler is entered as normal.</p> <p>The return link in R14_irq or R14_fiq contains the address of the MCR instruction plus eight, so the typical instruction used for interrupt return (SUBS PC,R14,#4) returns to the instruction following the MCR.</p>

## Cache operation functions

This table lists the cache operation functions and associated data and instruction formats for R7.

Function/operation	Data format	Instruction
Invalidate ICache and DCache	SBZ	MCR p15, 0, Rd, c7, c7, 0
Invalidate ICache	SBZ	MCR p15, 0, Rd, c7, c5, 0
Invalidate ICache single entry (MVA)	MVA	MCR p15, 0, Rd, c7, c5, 1
Invalidate ICache single entry (set/way)	Set/Way	MCR p15, 0, Rd, c7, c5, 2
Prefetch ICache line (MVA)	MVA	MCR p15, 0, Rd, c7, c13, 1
Invalidate DCache	SBZ	MCR p15, 0, Rd, c7, c6, 0
Invalidate DCache single entry (MVA)	MVA	MCR p15, 0, Rd, c7, c6, 1
Invalidate DCache single entry (set/way)	Set/Way	MCR p15, 0, Rd, c7, c6, 2
Clean DCache single entry (MVA)	MVA	MCR p15, 0, Rd, c7, c10, 1
Clean DCache single entry (set/way)	Set/Way	MCR p15, 0, Rd, c7, c10, 2
Test and clean DCache	N/A	MRC p15, 0, Rd, c7, c10, 3
Clean and invalidate DCache entry (MVA)	MVA	MCR p15, 0, Rd, c7, c14, 1
Clean and invalidate DCache entry (set/way)	Set/Way	MCR p15, 0, Rd, c7, c14, 2
Test, clean, and invalidate DCache	N/A	MRC p15, 0, Rd, c7, c14, 3

Function/operation	Data format	Instruction
Drain write buffer	SBZ	MCR p15, 0, Rd, c7, c10, 4
Wait for interrupt	SBZ	MCR p15, 0, Rd, c7, c0, 4

### Modified virtual address format (MVA)

This is the modified virtual address format for  $R_d$  for the CP15 R7 MCR operations.

- The tag, set, and word fields define the MVA.
- For all cache operations, the word field SHOULD BE ZERO.

### Set/Way format

This is the Set/Way format for  $R_d$  for the CP15 R7 MCR operations.

- A and S are the base-two logarithms of the associativity and the number of sets.
- The set, way, and word files define the format.
- For all of the cache operations, word SHOULD BE ZERO.

### Set/Way example

For example, a 16 KB cache, 4-way set associative, 8-word line results in the following:

- $A = \log_2 \text{associativity} = \log_2 4 = 2$
- $S = \log_2 \text{NSETS}$  where  
 $\text{NSETS} = \text{cache size in bytes} / \text{associativity} / \text{line length in bytes}$   
 $\text{NSETS} = 16384 / 4 / 32 = 128$   
 Result:  $S = \log_2 128 = 7$

### Test and clean DCache instructions

The test and clean DCache instruction provides an efficient way to clean the entire DCache, using a simple loop. The test and clean DCache instruction tests a number of lines in the DCache to determine whether any of them are dirty. If any dirty lines are found, one of those lines is cleaned. The test and clean DCache instruction also returns the status of the entire DCache in bit 30.

**Note:** The test and clean DCache instruction MRC p15, 0, r15, c7, c10, 3 is a special encoding that uses r15 as a destination operand. The PC is not changed by using this instruction, however. This MRC instruction also sets the condition code flags.

If the cache contains any dirty lines, bit 30 is set to 0. If the cache contains no dirty lines, bit 30 is set to 1. Use the following loop to clean the entire cache:

```
tc_loop:      MRC p15, 0, r15, c7, c10, 3; test and clean
              BNE tc_loop
```

### Test, clean, and invalidate DCache instruction

The test, clean, and invalidate DCache instruction is the same as the test and clean DCache instruction except that when the entire cache has been cleaned, it is invalidated. Use the following loop to test, clean, and invalidate the entire DCache:

```
tci_loop:     MRC p15, 0, r15, c7, c14, 3; test clean and invalidate
              BNE tci_loop
```

## R8:TLB Operations register

Register R8 is a write-only register that controls the translation lookaside buffer (TLB). There is a single TLB used to hold entries for both data and instructions. The TLB is divided into two parts:

- Set-associative
- Fully-associative

The *fully-associative* part (also referred to as the *lockdown* part of the TLB) stores entries to be locked down. Entries held in the lockdown part of the register are preserved during an invalidate-TLB operation. Entries can be removed from the lockdown TLB using an invalidate TLB single entry operation.

### TLB operations

There are six TLB operations; the function to be performed is selected by the opcode\_2 and CRm fields in the MCR instruction used to write register R8. Writing other opcode\_2 or CRm values is UNPREDICTABLE. Reading from this register is UNPREDICTABLE.

### TLB operation instructions

Use these instruction to perform TLB operations.

Operation	Data	Instruction
Invalidate set-associative TLB	SBZ	MCR p15, 0, Rd, c8, c7, 0
Invalidate single entry	SBZ	MCR p15, 0, Rd, c8, c7, 1
Invalidate set-associative TLB	SBZ	MCR p15, 0, Rd, c8, c5, 0
Invalidate single entry	MVA	MCR p15, 0, Rd, c8, c5, 1

Operation	Data	Instruction
Invalidate set-associative TLB	SBZ	MCR p15, 0, Rd, c8, c6, 0
Invalidate single entry	MVA	MCR p15, 0, Rd, c8, c6, 1

- The *invalidate TLB operations* invalidate all the unpreserved entries in the TLB.
- The *invalidate TLB single entry operations* invalidate any TLB entry corresponding to the modified virtual address given in Rd, regardless of its preserved state. See "R10: TLB Lockdown register," beginning on page 99, for an explanation of how to preserve TLB entries.

### Modified virtual address format (MVA)

This is the modified virtual address format used for invalid TLB single entry operations.

**Note:** If either small or large pages are used, and these pages contain subpage access permissions that are different, you must use four invalidate TLB single entry operations, with the MVA set to each subpage, to invalidate all information related to that page held in a TLB.

## R9: Cache Lockdown register

Register R9 access the cache lockdown registers. Access this register using CRm = 0.

### Cache ways

The Cache Lockdown register uses a cache-way-based locking scheme (format C) that allows you to control each cache way independently.

These registers allow you to control which cache-ways of the four-way cache are used for the allocation on a linefill. When the registers are defined, subsequent linefills are placed only in the specified target cache way. This gives you some control over the cache pollution cause by particular applications, and provides a traditional lockdown operation for locking critical code into the cache.

A locking bit for each cache way determines whether the normal cache allocation is allowed to access that cache way (see "Cache Lockdown register L bits" on page 97). A maximum of three cache ways of the four-way associative cache can be locked, ensuring that normal cache line replacement is performed.

**Note:** If no cache ways have the L bit set to 0, cache way 3 is used for all linefills.

## Instruction or data lockdown register

The first four bits of this register determine the L bit for the associated cache way. The opcode\_2 field of the MRC or MCR instruction determines whether the instruction or data lockdown register is accessed:

opcode_2=0	Selects the DCache Lockdown register, or the Unified Cache Lockdown register if a unified cache is implemented. The ARM926EJ-S processor has separate DCache and ICache.
opcode_2=1	Selects the ICache Lockdown register.

## Access instructions

Use these instructions to access the CacheLockdown register.

Function	Data	Instruction
Read DCache Lockdown register	L bits	MRC p15, 0, Rd, c9, c0, 0
Write DCache Lockdown register	L bits	MCR p15, 0, Rd, c9, c0, 0
Read ICache Lockdown register	L bits	MRC p15, 0, Rd, c9, c0, 1
Write ICache Lockdown register	L bits	MCR p15, 0, Rd, c9, c0, 1

## Modifying the Cache Lockdown register

You must modify the Cache Lockdown register using a modify-read-write sequence; for example:

```
MRC p15, 0, Rn, c9, c0, 1;
ORR Rn, Rn, 0x01;
MCR p15, 0, Rn, c9, c0, 1;
```

This sequence sets the L bit to 1 for way 0 of the ICache.

## Register format

This is the format for the Cache Lockdown register.

31	16	15	4	3	0
SBZ/UNP			SB0		L bits (cache ways 0 to 3)

## Cache Lockdown register L bits

This table shows the format of the Cache Lockdown register L bits. All cache ways are available for allocation from reset.

Bits	4-way associative	Notes
[31:16]	UNP/SBZ	Reserved
[15:4]	0xFFF	SBO

Bits	4-way associative	Notes
[3]	L bit for way 3	Bits [3:0] are the L bits for each cache way: 0 Allocation to the cache way is determined by the standard replacement algorithm (reset state)
[2]	L bit for way 2	
[1]	L bit for way 1	1 No allocation is performed to this way
[0]	L bit for way 0	

### Lockdown cache: Specific loading of addresses into a cache-way

Use this procedure to lockdown cache. The procedure to lock down code and data into way *i* of cache, with *N* ways, using format C, makes it impossible to allocate to any cache way other than the target cache way:

- 1 Ensure that no processor exceptions can occur during the execution of this procedure; for example, disable interrupts. If this is not possible, all code and data used by any exception handlers must be treated as code and data as in Steps 2 and 3.
- 2 If an ICache way is being locked down, be sure that all the code executed by the lockdown procedure is in an uncachable area of memory or in an already locked cache way.
- 3 If a DCache way is being locked down, be sure that all data used by the lockdown procedure is in an uncachable area of memory or is in an already locked cache way.
- 4 Ensure that the data/instructions that are to be locked down are in a cachable area of memory.
- 5 Be sure that the data/instructions that are to be locked down are not already in the cache. Use the Cache Operations register (R7) clean and/or invalidate functions to ensure this.
- 6 Write these settings to the Cache Lockdown register (R9), to enable allocation to the target cache way:
 

CRm = 0  
Set L == 0 for bit *i*  
Set L == 1 for all other bits
- 7 For each of the cache lines to be locked down in cache way *i*:
  - If a DCache is being locked down, use an LDR instruction to load a word from the memory cache line to ensure that the memory cache line is loaded into the cache.
  - If an ICache is being locked down, use the Cache Operations register (R7) MCR prefetch ICache line (<CRm>==c13, <opcode2>==1) to fetch the memory cache line into the cache.

- 8 Write  $\langle CR_m \rangle = 0$  to Cache Lockdown register (R9), setting  $L = 1$  for bit  $i$  and restoring all other bits to the values they had before the lockdown routine was started.

### Cache unlock procedure

To unlock the locked down portion of the cache, write to Cache Lockdown register (R9) setting  $L = 0$  for the appropriate bit. The following sequence, for example, sets the L bit to 0 for way 0 of the ICache, unlocking way 0:

```
MRC p15, 0, Rn, c9, c0, 1;
BIC Rn, Rn, 0x01;
MCR p15, 0, Rn, c9, c0, 1;
```

## R10:TLB Lockdown register

The TLB Lockdown register controls where hardware page table walks place the TLB entry — in the set associative region or the lockdown region of the TLB. If the TLB entry is put in the lockdown region, the register indicates which entry is written. The TLB lockdown region contains eight entries (see the discussion of the TLB structure in "TLB structure," beginning on page 124, for more information).

### Register format

31	29	28	26	25		0
SBZ		Victim		SBZ/UNP		P

### P bit

When writing the TLB Lockdown register, the value in the P bit (D0) determines in which region the TLB entry is placed:

P=0	Subsequent hardware page table walks place the TLNB entry in the set associative region of the TLB.
P=1	Subsequent hardware page table walks place the TLB entry in the lockdown region at the entry specified by the victim, in the range 0–7.

### Invalidate operation

TLB entries in the lockdown region are preserved so invalidate-TLB operations only invalidate the unpreserved entries in the TLB; that is, those entries in the set-associative region. Invalidate-TLB single entry operations invalidate any TLB entry corresponding to the modified virtual address given in  $R_d$ , regardless of the entry's preserved state; that is, whether they are in lockdown or set-associative TLB regions. See "R8:TLB Operations register" on page 95 for a description of the TLB-invalidate operations.

**Programming instructions**

Use these instructions to program the TLB Lockdown register:

Function	Instruction
Read data TLB lockdown victim	MRC p15, 0, Rd, c10, c0, 0
Write data TLB lockdown victim	MCR p15, 0, Rd, c10, c0, 0

The victim automatically increments after any table walk that results in an entry being written into the lockdown part of the TLB.

**Note:** It is not possible for a lockdown entry to map entirely either small or large pages, unless all subpage access permissions are the same. Entries can still be written into the lockdown region, but the address range that is mapped covers only the subpage corresponding to the address that was used to perform the page table walk.

**Sample code sequence**

This example shows the code sequence that locks down an entry to the current victim.

```

ADR r1,LockAddr           ; set R1 to the value of the address to be locked down
MCR p15,0,r1,c8,c7,1      ; invalidate TLB single entry to ensure that
                           ; LockAddr is not already in the TLB

MRC p15,0,r0,c10,c0,0     ; read the lockdown register
ORR r0,r0,#1              ; set the preserve bit
MCR p15,0,r0,c10,c0,0     ; write to the lockdown register
LDR r1,[r1]               ; TLB will miss, and entry will be loaded
MRC p15,0,r0,c10,c0,0     ; read the lockdown register (victim will have
                           ; incremented
BIC r0,r0,#1              ; clear preserve bit
MCR p15,0,r0,c10,c0,0     ; write to the lockdown register

```

**R11 and R12 registers**

Accessing (reading or writing) these registers causes UNPREDICTABLE behavior.

**R13:Process ID register**

The Process ID register accesses the process identifier registers. The register accessed depends on the value on the `opcode_2` field:

<code>opcode_2=0</code>	Selects the <i>Fast Context Switch Extension (FCSE) Process Identifier (PID)</i> register.
-------------------------	--

opcode\_2=1                      Selects the context ID register.

Use the Process ID register to determine the process that is currently running. The process identifier is set to 0 at reset.

## FCSE PID register

Addresses issued by the ARM926EJ-S core, in the range 0 to 32 MB, are translated according to the value contained in the FCSE PID register. Address A becomes  $A + (\text{FCSE PID} \times 32 \text{ MB})$ ; it is this modified address that the MMU and caches see. Addresses above 32 MB are not modified. The FCSE PID is a 7-bit field, which allows 128 x 32 MB processes to be mapped.

If the FCSE PID is 0, there is a flat mapping between the virtual addresses output by the ARM926EJ-S core and the modified virtual addresses used by the caches and MMU. The FCSE PID is set to 0 at system reset.

If the MMU is disabled, there is no FCSE address translation.

FCSE translation is not applied for addresses used for entry-based cache or TLB maintenance operations. For these operations,  $VA=MVA$ .

## Access instructions

Use these instructions to access the FCSE PID register:

Function	Data	ARM instruction
Read FCSE PID	FCSE PID	MRC p15,0,Rd,c13,c0,0
Write FCSE PID	FCSE PID	MCR p15,0,Rd,c13,c0,0

## Register format

This is the format of the FCSE PID register.

## Performing a fast context switch

You can perform a fast context switch by writing to the Process ID register (R13) with opcode\_2 set to 0. The contents of the caches and the TLB do not have to be flushed after a fast context switch because they still hold address tags. The two instructions after the FCSE PID has been written have been fetched with the old FCSE PID, as shown in this code example:

```
{FCSE PID = 0}
MOV r0, #1:SHL:25      ;Fetched with FCSE PID = 0
MCR p15,0,r0,c13,c0,0  ;Fetched with FCSE PID = 0
A1                      ;Fetched with FCSE PID = 0
A2                      ;Fetched with FCSE PID = 0
A3                      ;Fetched with FCSE PID = 1
```

## Context ID register

## Access instructions

Function	Data	ARM instruction
Read context ID	Context ID	MRC p15,0,Rd,c13,c0,1
Write context ID	Context ID	MCR p15,0,Rd,c13,c0,1

## Hardware Reference NS9215

- Software emulation within the ARM-optimized JVM, which addresses the remaining 20% of the Java byte codes.

## DSP

The ARM926EJ-S processor core provides enhanced DSP capability. Multiply instructions are processed using a single cycle 32x16 implementation. There are 32x32, 32x16, and 16x16 multiply instructions, or *Multiply Accumulate (MAC)*, and the pipeline allows one multiply to start each cycle. Saturating arithmetic improves efficiency by automatically selecting saturating behavior during execution, and is used to set limits on signal processing calculations to minimize the effect of noise or signal errors. All of these instructions are beneficial for algorithms that implement the following:

- GSM protocols
- FFT
- State space servo control

## Memory Management Unit (MMU)

The MMU provides virtual memory features required by systems operating on platforms such as WindowsCE or Linux. A single set of two-level page tables stored in main memory control the address translation, permission checks, and memory region attributes for both data and instruction accesses. The MMU uses a single, unified *Translation Lookaside Buffer (TLB)* to cache the information held in the page tables. TLB entries can be locked down to ensure that a memory access to a given region never incurs the penalty of a page table walk.

### MMU Features

- Standard ARM926EJ-S architecture MMU mapping sizes, domains, and access protection scheme.
- Mapping sizes, as follows:
  - 1 MB for sections
  - 64 KB for large pages
  - 4 KB for small pages
  - 1 KB for tiny pages
- Access permissions for large pages and small pages can be specified separately for each quarter of the page (subpage permissions).
- Hardware page table walks.

- Invalidate entire TLB using R8: TLB Operations register (see “R8:TLB Operations register” on page 95).
- Invalidate TLB entry selected by MVA, using R8: TLB Operations register (see “R8:TLB Operations register” on page 95).
- Lockdown of TLB entries using R10: TLB Lockdown register (see “R10:TLB Lockdown register” on page 99).

### **Access permissions and domains**

For large and small pages, access permissions are defined for each subpage (1 KB for small pages, 16 KB for large pages). Sections and tiny pages have a single set of access permissions.

All regions of memory have an associated domain. A domain is the primary access control mechanism for a region of memory. It defines the conditions necessary for an access to proceed. The domain determines whether:

- Access permissions are used to qualify the access.
- The access is unconditionally allowed to proceed.
- The access is unconditionally aborted.

In the latter two cases, the access permission attributes are ignored.

There are 16 domains, which are configured using R3: Domain Access Control register (see “R3:Domain Access Control register” on page 89).

### **Translated entries**

The TLB caches translated entries. During CPU memory accesses, the TLB provides the protection information to the access control logic.

When the TLB contains a translated entry for the modified virtual address (MVA), the access control logic determines whether:

- Access is permitted and an off-chip access is required — the MMU outputs the appropriate physical address corresponding to the MVA.
- Access is permitted and an off-chip access is not required — the cache services the access.
- Access is not permitted — the MMU signals the CPU core to abort.

If the TLB misses (it does not contain an entry for the MVA), the translation table walk hardware is invoked to retrieve the translation information from a translation table in physical memory. When retrieved, the translation information is written into the TLB, possibly overwriting an existing value.

At reset, the MMU is turned off, no address mapping occurs, and all regions are marked as noncachable and nonbufferable.

## MMU program accessible registers

This table shows the CP15 registers that are used in conjunction with page table descriptors stored in memory to determine MMU operation.

Register	Bits	Description
R1: Control register	M, A, S, R	Contains bits to enable the MMU (M bit), enable data address alignment checks (A bit), and to control the access protection scheme (S bit and R bit).
R2: Translation Table Base register	[31:14]	Holds the physical address of the base of the translation table maintained in main memory. This base address must be on a 16 KB boundary.
R3: Domain Access Control register	[31:0]	Comprises 16 two-bit fields. Each field defines the access control attributes for one of 16 domains (D15 to D00).
R5: Fault Status registers, IFSR and DFSR	[7:0]	Indicates the cause of a data or prefetch abort, and the domain number of the aborted access when an abort occurs. Bits [7:4] specify which of the 16 domains (D15 to D00) was being accessed when a fault occurred. Bits [3:0] indicate the type of access being attempted. The value of all other bits is UNPREDICTABLE. The encoding of these bits is shown in “Priority encoding table” on page 118).
R6: Fault Address register	[31:0]	Holds the MVA associated with the access that caused the data abort. See “Priority encoding table” on page 118 for details of the address stored for each type of fault.
R8: TLB Operations register	[31:0]	Performs TLB maintenance operations. These are either invalidating all the (unpreserved) entries in the TLB, or invalidating a specific entry.
R10: TLB Lockdown register	[28:26] and 0	Enables specific page table entries to be locked into the TLB. Locking entries in the TLB guarantees that accesses to the locked page or section can proceed without incurring the time penalty of a TLB miss. This enables the execution latency for time-critical pieces of code, such as interrupt handlers, to be minimized.

All CP15 MMU registers, except R8: TLB Operations, contain state that can be read using MRC instructions, and can be written using MCR instructions. Registers R5 (Fault Status) and R6 (Fault Address) are also written by the MMU during an abort.

Writing to R8: TLB Operations causes the MMU to perform a TLB operation, to manipulate TLB entries. This register is write-only.

## Address translation

The virtual address (VA) generated by the CPU core is converted to a modified virtual address (MVA) by the FCSE (fast context switch extension) using the value held in CP15 R13: Process ID register. The MMU translates MVAs into physical addresses to access external memory, and also performs access permission checking.

The MMU table-walking hardware adds entries to the TLB. The translation information that comprises both the address translation data and the access permission data resides in a translation table located in physical memory. The MMU provides the logic for automatically traversing this translation table and loading entries into the TLB.

The number of stages in the hardware table walking and permission checking process is one or two, depending on whether the address is marked as a section-mapped access or a page-mapped access.

There are three sizes of page-mapped accesses and one size of section-mapped access. Page-mapped accesses are for large pages, small pages, and tiny pages.

The translation process always begins in the same way — with a level-one fetch. A section-mapped access requires only a level-one fetch, but a page-mapped access requires an additional level-two fetch.

### **Translation table base**

The hardware translation process is initiated when the TLB does not contain a translation for the requested MVA. R2: Translation Table Base (TTB) register points to the base address of a table in physical memory that contains section or page descriptors, or both. The 14 low-order bits [13:0] of the TTB register are UNPREDICTABLE on a read, and the table must reside on a 16 KB boundary.

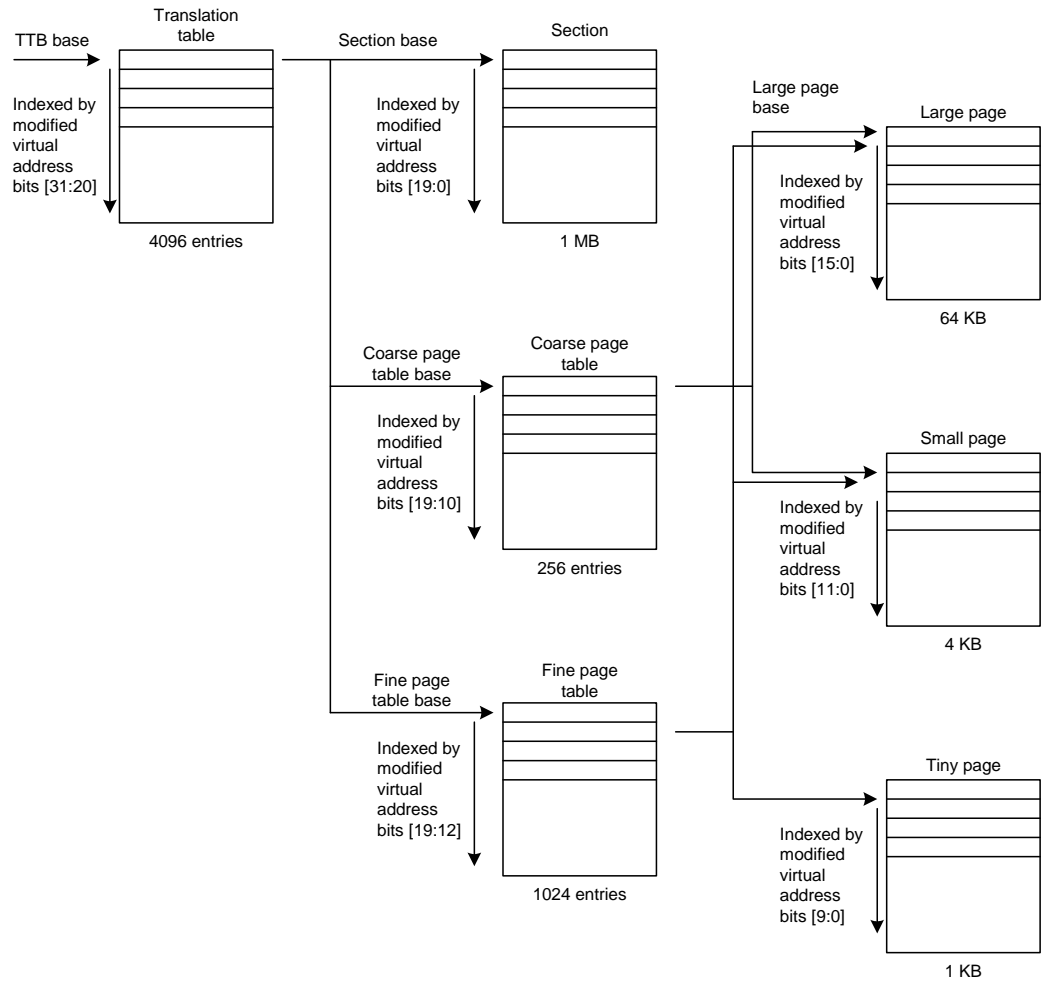

### **TTB register format**

The translation table has up to 4096 x 32-bit entries, each describing 1 MB of virtual memory. This allows up to 4 GB of virtual memory to be addressed.

## Table walk process

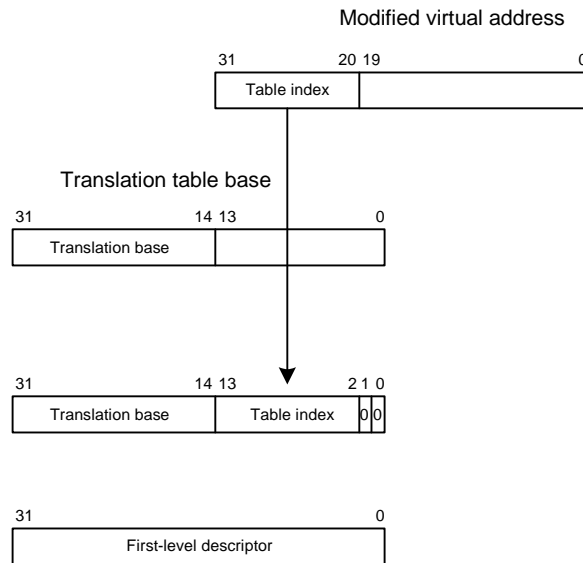

## First-level fetch

Bits [31:14] of the TTB register are concatenated with bits [31:20] of the MVA to produce a 30-bit address.

## First-level fetch concatenation and address

This address selects a 4-byte translation table entry. This is a first-level descriptor for either a section or a page.

## First-level descriptor

The first-level descriptor returned is a section description, a coarse page table descriptor, a fine page table descriptor, or is invalid. This is the format of a first-level descriptor.

31	20 19				12 11 10 9 8				5 4 3 2		1	0		
												0	0	Fault
Coarse page table base address									Domain	1		0	1	Coarse page table
Section base address						AP		Domain	1	C	B	1	0	Section
Fine page table base address								Domain	1			1	1	Fine page table

A section descriptor provides the base address of a 1 MB block of memory.

## Page table descriptors

The page table descriptors provide the base address of a page table that contains second-level descriptors. There are two page-table sizes:

- **Coarse page tables**, which have 256 entries and split the 1 MB that the table describes into 4 KB blocks.
- **Fine page tables**, which have 1024 entries and split the 1 MB that the table describes into 1 KB blocks.

### First-level descriptor bit assignments: Priority encoding of fault status

Bits			
Section	Coarse	Fine	Description
[31:20]	[31:10]	[31:12]	Forms the corresponding bits of the physical address.
[19:12]	----	---	SHOULD BE ZERO
[11:10]	---	---	Access permission bits. See “Access permissions and domains” on page 104 and “Fault Address and Fault Status registers” on page 117 for information about interpreting the access permission bits.
9	9	[11:9]	SHOULD BE ZERO
[8:5]	[8:5]	[8:5]	Domain control bits
4	4	4	Must be 1.
[3:2]	---	---	Bits C and B indicate whether the area of memory mapped by this page is treated as write-back cachable, write-through cachable, noncached buffered, or noncached nonbuffered.
---	[3:2]	[3:2]	SHOULD BE ZERO
[1:0]	[1:0]	[1:0]	These bits indicate the page size and validity, and are interpreted as shown in “First-level descriptor bit assignments: Priority encoding of fault status” on page 109.

### First-level descriptor bit assignments: Interpreting first level descriptor bits [1:0]

Value	Meaning	Description
0 0	Invalid	Generates a section translation fault.
0 1	Coarse page table	Indicates that this is a coarse page table descriptor.
1 0	Section	Indicates that this is a section descriptor.
1 1	Fine page table	Indicates that this is a fine page table descriptor.

### Section descriptor

A section descriptor provides the base address of a 1 MB block of memory.

### Section descriptor format

31	20	19	12	11	10	9	8	5	4	3	2	1	0	
Section base address			SBZ			AP	S B Z	Domain		1	C	B	1	0

### Section descriptor bit description

Bits	Description
[31:20]	Forms the corresponding bits of the physical address for a section.
[19:12]	Always written as 0.
[11:10]	Specify the access permissions for this section.
[09]	Always written as 0.
[8:5]	Specifies one of the 16 possible domains (held in the Domain and Access Control register) that contain the primary access controls.
4	Should be written as 1, for backwards compatibility.
[3:2]	Indicate if the area of memory mapped by this section is treated as writeback cachable, write-through cachable, noncached buffered, or noncached nonbuffered.
[1:0]	Must be <i>10</i> to indicate a section descriptor.

### Coarse page table descriptor

A coarse page table descriptor provides the base address of a page table that contains second-level descriptors for either large page or small page accesses. Coarse page tables have 256 entries, splitting the 1 MB that the table describes into 4 KB blocks.

**Note:** If a coarse page table descriptor is returned from the first-level fetch, a second-level fetch is initiated.

### Coarse page table descriptor format

31	10	9	8	5	4	3	2	1	0
Coarse page table base address				S B Z	Domain	1	SBZ	0	1

### Coarse page table descriptor bit description

Bits	Description
[31:10]	Forms the base for referencing the second-level descriptor (the coarse page table index for the entry derived from the MVA).
9	Always written as 0.
[8:5]	Specifies one of the 16 possible domains (held in the Domain Access Control registers) that contain the primary access controls.
4	Always written as 1.
[3:2]	Always written as 0.
[1:0]	Must be <i>01</i> to indicate a coarse page descriptor.

### Fine page table descriptor

A fine page table descriptor provides the base address of a page table that contains second-level descriptors for large page, small page, or tiny page accesses. Fine

page tables have 1024 entries, splitting the 1 MB that the table describes into 1 KB blocks. The next two sections show the format of a fine page table descriptor and define the fine page table descriptor bit assignments.

**Note:** If a fine page table descriptor is returned from the first-level fetch, a second-level fetch is initiated.

Fine page table  
descriptor format

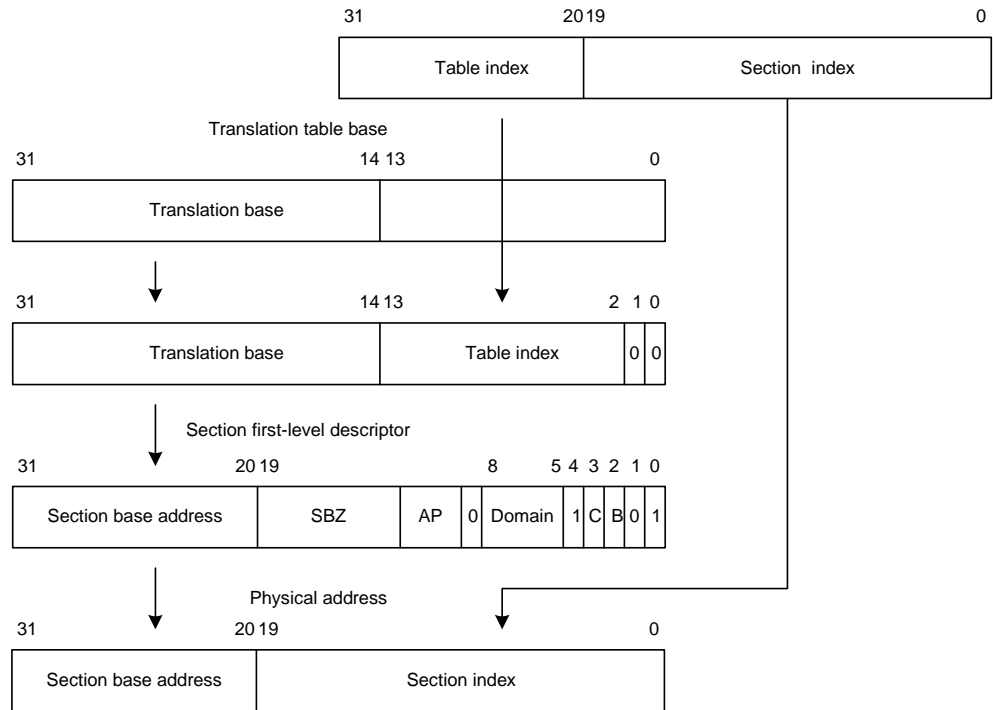

Fine page table  
descriptor bit  
description

Bits	Description
[31:12]	Forms the base for referencing the second-level descriptor (the fine page table index for the entry is derived from the MVA).
[11:9]	Always written as 0.
[8:5]	Specifies one of the 16 possible domains (held in the Domain Access Control register) that contain primary access controls.
4	Always written as 1.
[3:2]	Always written as 0.
[1:0]	Must be 11 to indicate a fine page table descriptor.

Translating  
section references

This figure illustrates the complete section translation sequence.

### Second-level descriptor

The base address of the page table to be used is determined by the descriptor returned (if any) from a first-level fetch — either a coarse page table descriptor or a fine page table descriptor. The page table is then accessed and a second-level descriptor returned.

### Second-level descriptor format

31	16	15	12	11	10	9	8	7	6	5	4	3	2	1	0	
														0	0	Fault
Large page base address						AP3	AP2	AP1	AP0	C	B	0	1			Large page
Small page base address						AP3	AP2	AP1	AP0	C	B	1	0			Small page
Tiny page base address									AP	C	B	1	1			Tiny page

### Second-level descriptor pages

A second-level descriptor defines a tiny, small, or large page descriptor, or is invalid:

- A large page descriptor provides the base address of a 64 KB block of memory.
- A small page descriptor provides the base address of a 4 KB block of memory.

- A tiny page descriptor provides the base address of a 1 KB block of memory.

Coarse page tables provide base addresses for either small or large pages. Large page descriptors must be repeated in 16 consecutive entries. Small page descriptors must be repeated in each consecutive entry.

Fine page tables provide base addresses for large, small, or tiny pages. Large page descriptors must be repeated in 64 consecutive entries. Small page descriptors must be repeated in four consecutive entries. Tiny page descriptors must be repeated in each consecutive entry.

### Second-level descriptor bit assignments

Bits			
Large	Small	Tiny	Description
[31:16]	[31:12]	[31:10]	Form the corresponding bits of the physical address.
[15:12]	---	[9:6]	SHOULD BE ZERO
[11:4]	[11:4]	[5:4]	Access permission bits. See “Domain access control” on page 119 and “Fault checking sequence” on page 120 for information about interpreting the access permission bits.
[3:2]	[3:2]	[3:2]	Indicate whether the area of memory mapped by this page is treated as write-back cachable, write-through cachable, noncached buffered, and noncached nonbuffered.
[1:0]	[1:0]	[1:0]	Indicate the page size and validity, and are interpreted as shown in “First-level descriptor bit assignments: Interpreting first level descriptor bits [1:0]” on page 109.

### Second-level descriptor least significant bits

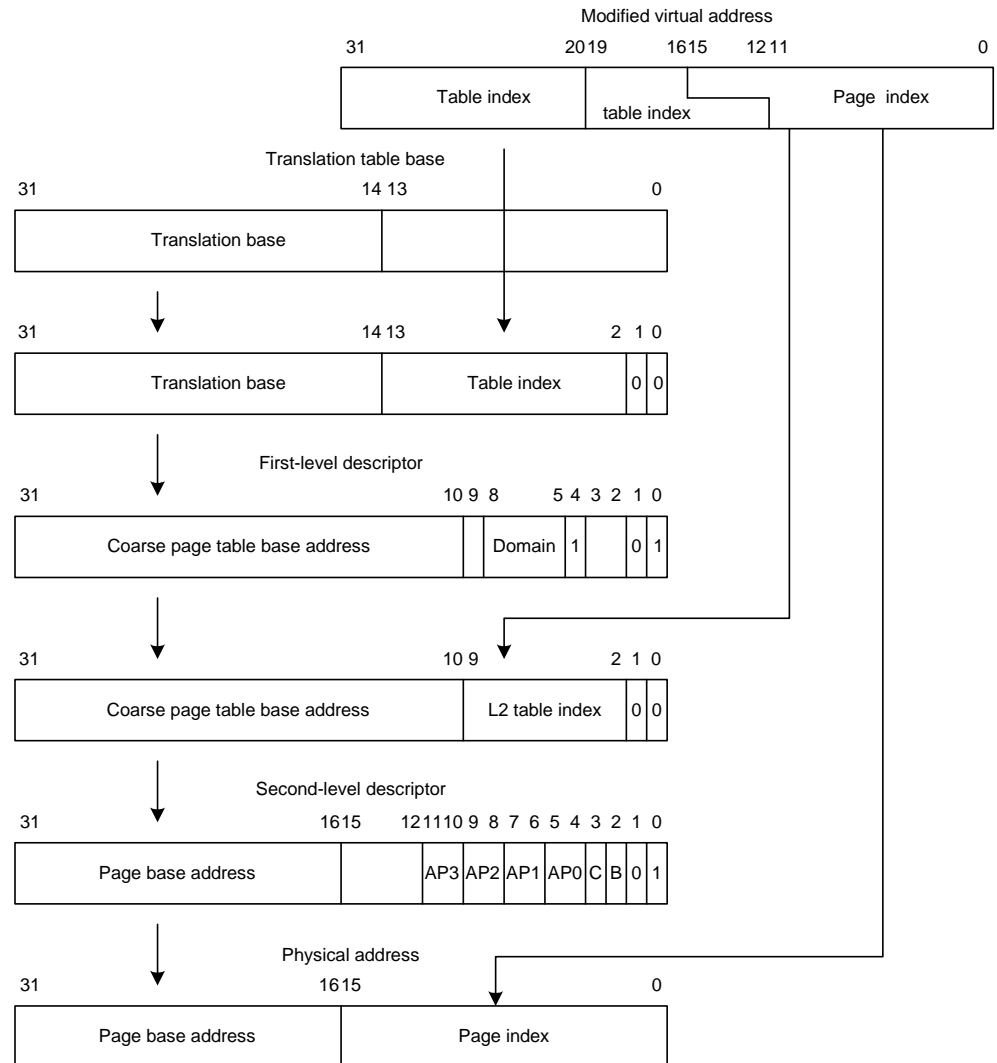

The two least significant bits of the second-level descriptor indicate the descriptor type, as shown in this table.

Value	Meaning	Description
0 0	Invalid	Generates a page translation fault.
0 1	Large page	Indicates that this is a 64 KB page.
1 0	Small page	Indicates that this is a 4 KB page.
1 1	Tiny page	Indicates that this is a 1 KB page.

**Note:** Tiny pages do not support subpage permissions and therefore have only one set of access permission bits.

## Translation sequence for large page references

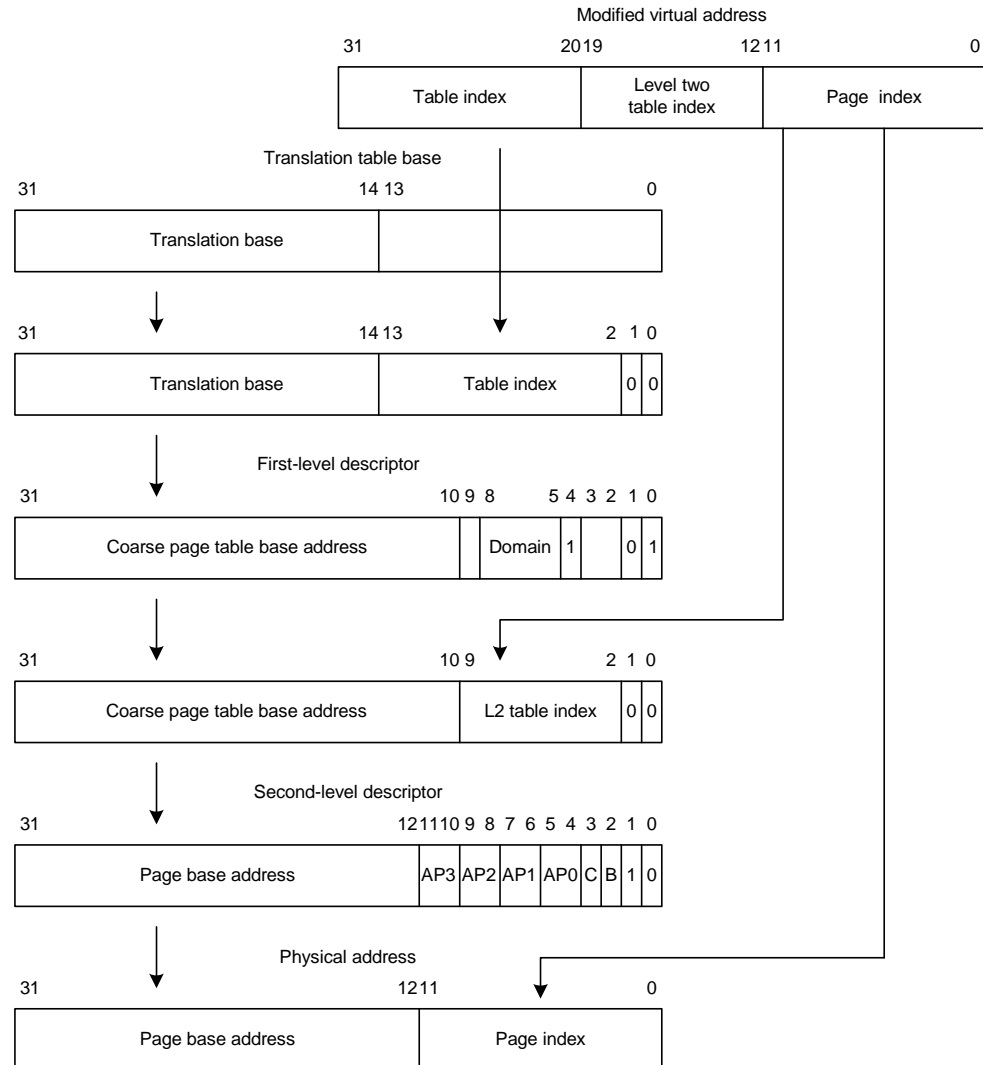

Because the upper four bits of the page index and low-order four bits of the coarse page table index overlap, each coarse page table entry for a large page must be duplicated 16 times (in consecutive memory locations) in the coarse page table.

If the large page descriptor is included in a fine page table, the high-order six bits of the page index and low-order six bits of the fine page table overlap. Each fine page table entry for a large page must be duplicated 64 times.

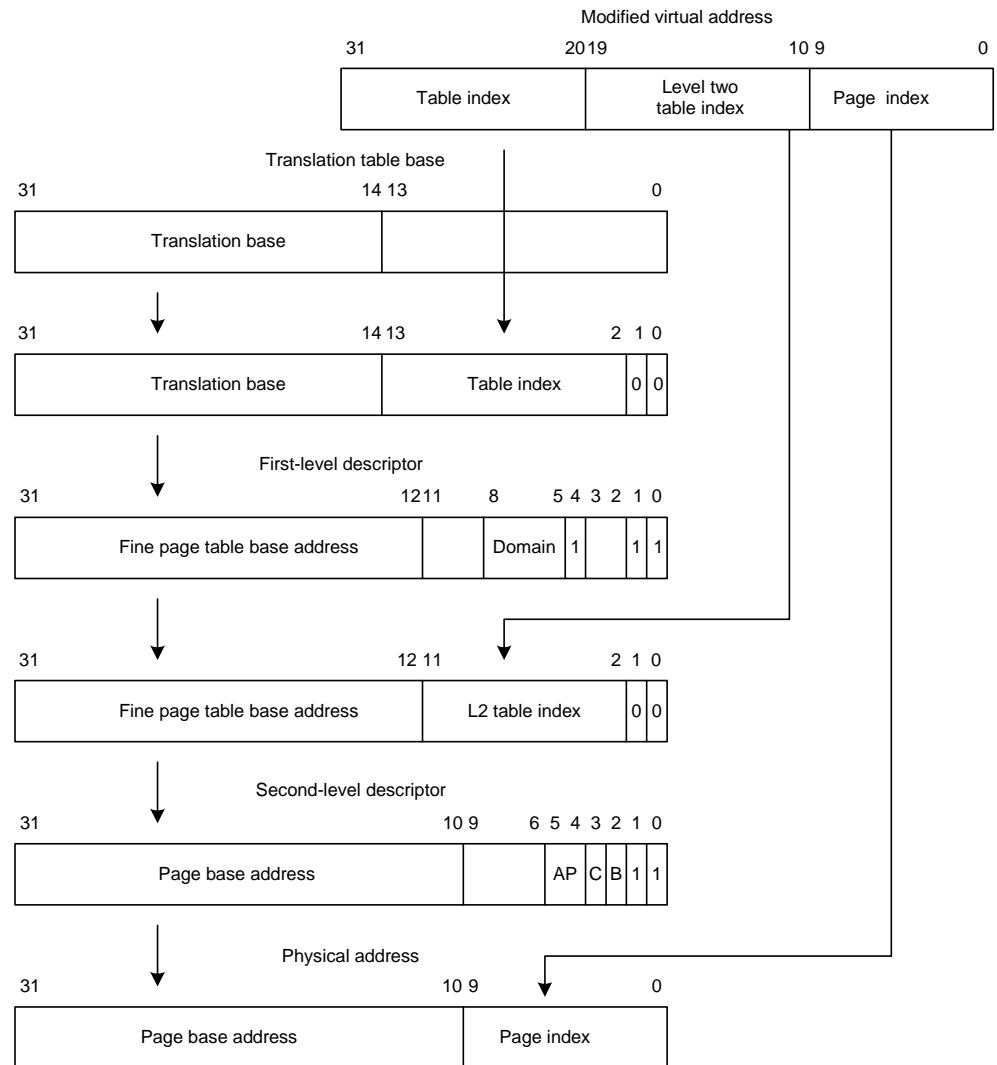

## Translating sequence for small page references

If a small page descriptor is included in a fine page table, the upper two bits of the page index and low-order two bits of the fine page table index overlap. Each fine page table entry for a small page must be duplicated four times.

## Translation sequence for tiny page references

Page translation involves one additional step beyond that of a section translation. The first-level descriptor is the fine page table descriptor; this points to the first-level descriptor.

**Note:** The domain specified in the first-level description and access permissions specified in the first-level description together determine whether the access has permissions to proceed. See “Domain access control” on page 119 for more information.

## Subpages

You can define access permissions for subpages of small and large pages. If, during a page table walk, a small or large page has a different subpage permission, only the subpage being accessed is written into the TLB. For example, a 16 KB (large page) subpage entry is written into the TLB if the subpage permission differs, and a 64 KB entry is put in the TLB if the subpage permissions are identical.

When you use subpage permissions and the page entry has to be invalidated, you must invalidate all four subpages separately.

## MMU faults and CPU aborts

The MMU generates an abort on these types of faults:

- Alignment faults (data accesses only)
- Translation faults
- Domain faults
- Permission faults

In addition, an external abort can be raised by the external system. This can happen only for access types that have the core synchronized to the external system:

- Page walks
- Noncached reads
- Nonbuffered writes
- Noncached read-lock-write sequence (SWP)

### Alignment fault checking

Alignment fault checking is enabled by the A bit in the R1: Control register.

Alignment fault checking is not affected by whether the MMU is enabled.

Translation, domain, and permission faults are generated only when the MMU is enabled.

The access control mechanisms of the MMU detect the conditions that produce these faults. If a fault is detected as a result of a memory access, the MMU aborts the access and signals the fault condition to the CPU core. The MMU retains status and address information about faults generated by the data accesses in the Data Fault Status register and Fault Address register (see “Fault Address and Fault Status registers” on page 117).

The MMU also retains status about faults generated by instruction fetches in the Instruction Fault Status register.

An access violation for a given memory access inhibits any corresponding external access to the AHB interface, with an abort returned to the CPU core.

### Fault Address and Fault Status registers

On a data abort, the MMU places an encoded four-bit value — the *fault status* — along with the four-bit encoded domain number in the Data Fault Status register. Similarly, on a prefetch abort, the MMU places an encoded four-bit value along with the four-bit encoded domain number in the Instruction Fault Status register. In addition, the MVA associated with the data abort is latched into the Fault Address

register. If an access violation simultaneously generates more than one source of abort, the aborts are encoded in the priority shown in the priority encoding table. The Fault Address register is not updated by faults caused by instruction prefetches.

### Priority encoding table

Priority	Source	Size	Status	Domain
Highest	Alignment	---	0b00x1	Invalid
	External abort on transmission	First level	0b1100	Invalid
		Second level	0b1110	Valid
	Translation	Section page	0b0101	Invalid
			0b0111	Valid
	Domain	Section page	0b1001	Valid
			0b1011	Valid
	Permission	Section page	0b1101	Valid
			0b1111	Valid
Lowest	External abort	Section page	0b1000	Valid
			0b1010	Valid

#### Notes:

- Alignment faults can write either 0b0001 or 0b0011 into Fault Status register [3:0].
- Invalid values can occur in the status bit encoding for domain faults. This happens when the fault is raised before a valid domain field has been read from a page table description.
- Aborts masked by a higher priority abort can be regenerated by fixing the cause of the higher priority abort, and repeating the access.
- Alignment faults are not possible for instruction fetches.
- The Instruction Fault Status register can be updated for instruction prefetch operations (MCR p15,0,Rd,c7,c13,1).

### Fault Address register (FAR)

For load and store instructions that can involve the transfer of more than one word (LDM/STM, STRD, and STC/LDC), the value written into the Fault Address register depends on the type of access and, for external aborts, on whether the access crosses a 1 KB boundary.

### FAR values for multi-word transfers

Domain	Fault Address register
Alignment	MVA of first aborted address in transfer
External abort on translation	MVA of first aborted address in transfer
Translation	MVA of first aborted address in transfer

Domain	Fault Address register
Domain	MVA of first aborted address in transfer
Permission	MVA of first aborted address in transfer
External abort for noncached reads, or nonbuffered writes	MVA of last address before 1KB boundary, if any word of the transfer before 1 KB boundary is externally aborted. MVA of last address in transfer if the first externally aborted word is after the 1 KB boundary.

### Compatibility issues

- To enable code to be ported easily to future architectures, it is recommended that no reliance is made on external abort behavior.
- The Instruction Fault Status register is intended for debugging purposes only.

## Domain access control

MMU accesses are controlled primarily through the use of domains. There are 16 domains, and each has a two-bit field to define access to it. Client users and Manager users are supported.

The domains are defined in the R3: Domain Access Control register; the register format in "R3: Domain Access Control register" on page 89 shows how the 32 bits of the register are allocated to define the 16 two-bit domains.

### Specifying access permissions

This table shows how the bits within each domain are defined to specify access permissions.

Value	Meaning	Description
0 0	No access	Any access generates a domain fault.
0 1	Client	Accesses are checked against the access permission bits in the section or page descriptor.
1 0	Reserved	Reserved. Currently behaves like <i>no access</i> mode.
1 1	Manager	Accesses are not checked against the access permission bits, so a permission fault cannot be generated.

### Interpreting access permission bits

This table shows how to interpret the *access permission (AP)* bits, and how the interpretation depends on the R and S bits in the R1: Control register (see "R1: Control register," beginning on page 86).

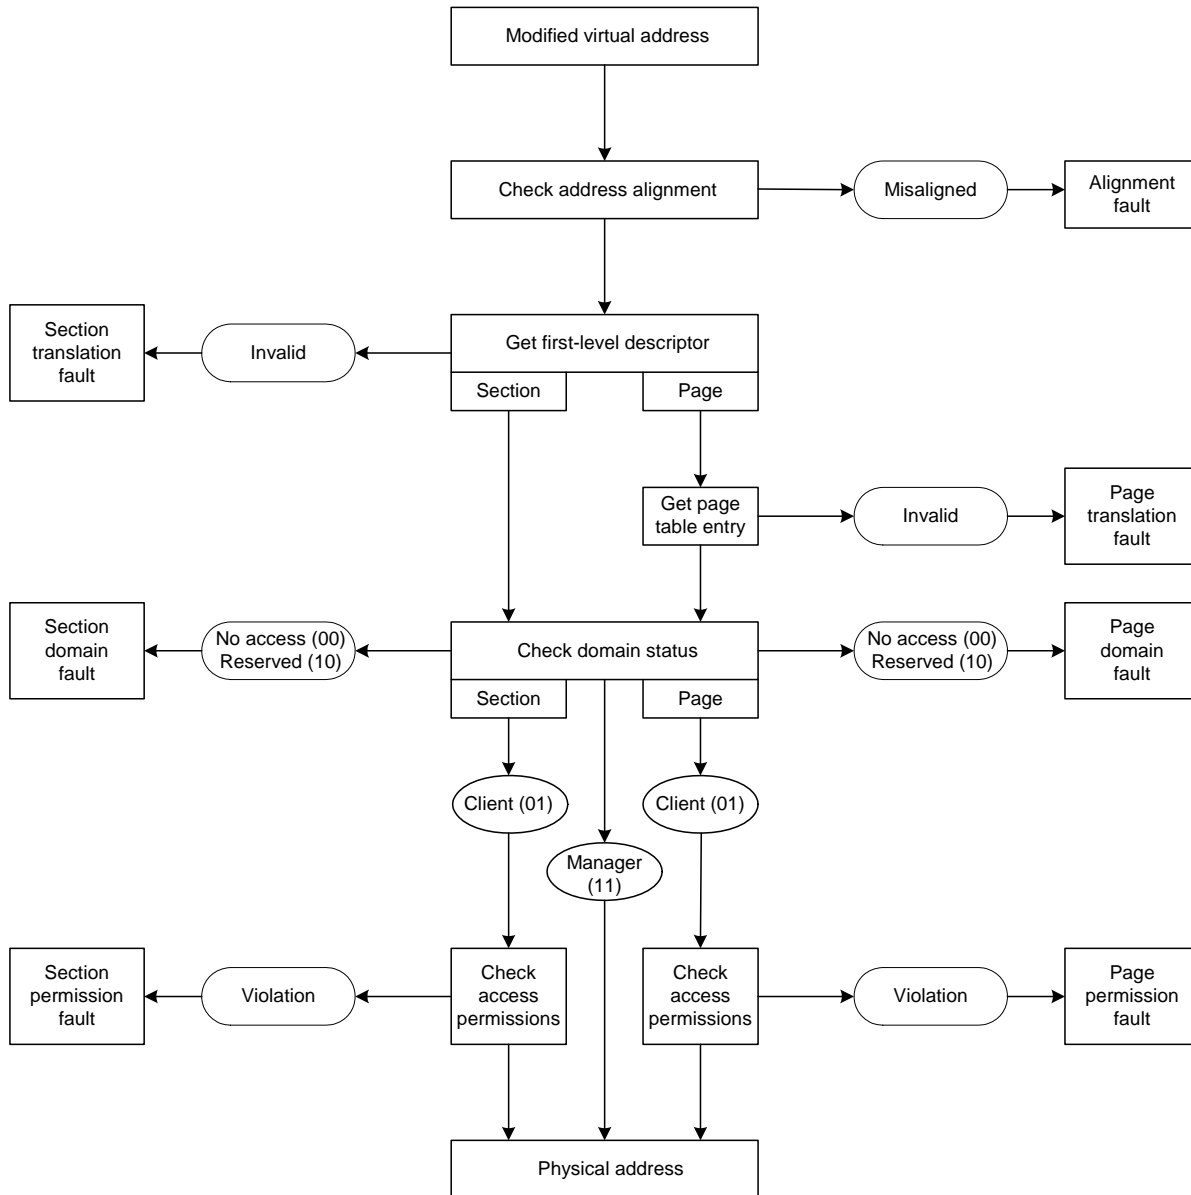

AP	S	R	Privileged permissions	User permissions
0 0	0	0	No access	No access
0 0	1	0	Read only	Read only
0 0	0	1	Read only	Read only
0 0	1	1	UNPREDICTABLE	UNPREDICTABLE
0 1	x	x	Read/write	No access
1 0	x	x	Read/write	Read only
1 1	x	x	Read/write	Read/write

## Fault checking sequence

The sequence the MMU uses to check for access faults is different for sections and pages. The next figure shows the sequence for both types of access.

The conditions that generate each of the faults are discussed in the following sections.

### Alignment faults

If alignment fault checking is enabled (the A bit in the R1: Control register is set; see "R1: Control register," beginning on page 86), the MMU generates an alignment fault on any data word access if the address is not word-aligned, or on any halfword access if the address is not halfword-aligned – irrespective of whether the MMU is enabled. An alignment fault is not generated on any instruction fetch or byte access.

**Note:** If an access generates an alignment fault, the access sequence aborts without reference to other permission checks.

### Translation faults

There are two types of translation fault: section and page.

- A section translation fault is generated if the level one descriptor is marked as invalid. This happens if bits [1:0] of the descriptor are both 0.
- A page translation fault is generated if the level one descriptor is marked as invalid. This happens if bits [1:0] of the descriptor are both 0.

### Domain faults

There are two types of domain faults: section and page.

- **Section:** The level one descriptor holds the four-bit domain field, which selects one of the 16 two-bit domains in the Domain Access Control register. The two bits of the specified domain are then checked for access permissions as described in “Interpreting access permission bits” on page 119. The domain is checked when the level one descriptor is returned.
- **Page:** The level one descriptor holds the four-bit domain field, which selects one of the 16 two-bit domains in the Domain Access Control register. The two bits of the specified domain are then checked for access permissions as described in “Interpreting access permission bits” on page 119. The domain is checked when the level one descriptor is returned.

If the specified access is either *no access* (00) or *reserved* (10), either a section domain fault or a page domain fault occurs.

### Permission faults

If the two-bit domain field returns *client* (01), access permissions are checked as follows:

- **Section:** If the level one descriptor defines a section-mapped access, the AP bits of the descriptor define whether the access is allowed, per “Interpreting access permission bits” on page 119. The interpretation depends on the setting of the S and R bits (see “R1: Control register,” beginning on page 86). If the access is not allowed, a section permission fault is generated.
- **Large page or small page:** If the level one descriptor defines a page-mapped access and the level two descriptor is for a large or small page, four access permission fields (AP3 to AP0) are specified, each corresponding to one quarter of the page.

For small pages, AP3 is selected by the top 1 KB of the page and AP0 is selected by the bottom 1 KB of the page.

For large pages, AP3 is selected by the top 16 KB of the page and AP0 is selected by the bottom 16 KB of the page. The selected AP bits are then

interpreted in the same way as for a section (see “Interpreting access permission bits” on page 119).

The only difference is that the fault generated is a page permission fault.

- **Tiny page:** If the level one descriptor defines a page-mapped access and the level two descriptor is for a tiny page, the AP bits of the level one descriptor define whether the access is allowed in the same way as for a section. The fault generated is a page permission fault.

## External aborts

In addition to MMU-generated aborts, external aborts can be generated for certain types of access that involve transfers over the AHB bus. These aborts can be used to flag errors on external memory accesses. Not all accesses can be aborted in this way, however.

These accesses can be aborted externally:

- Page walks
- Noncached reads
- Nonbuffered writes
- Noncached read-lock-write (SWP) sequence

For a read-lock-write (SWP) sequence, the write is always attempted if the read externally aborts.

A swap to an NCB region is forced to have precisely the same behavior as a swap to an NCNB region. This means that the write part of a swap to an NCB region can be aborted externally.

## Enabling and disabling the MMU

### Enabling the MMU

Before enabling the MMU using the R1: Control register, you must perform these steps:

- 1 Program the R2: Translation Table Base register and the R3: Domain Access Control register.
- 2 Program first-level and second-level page tables as required, ensuring that a valid translation table is placed in memory at the location specified by the Translation Table Base register.

When these steps have been performed, you can enable the MMU by setting R1: Control register bit 0 (the M bit) to high.

Care must be taken if the translated address differs from the untranslated address, because several instructions following the enabling of the MMU might have been prefetched with MMU off (VA=MVA=PA). If this happens, enabling the MMU can be considered as a branch with delayed execution. A similar situation occurs when the MMU is disabled. Consider this code sequence:

```
MRC p15, 0, R1, c1, C0, 0      ; Read control register
ORR R1, #0x1                   ; Set M bit
MCR p15, 0, R1, C1, C0, 0      ; Write control register and enable MMU
Fetch Flat
Fetch Flat
Fetch Translated
```

**Note:** Because the same register (R1: Control register) controls the enabling of ICache, DCache, and the MMU, all three can be enabled using a single MCR instruction.

### Disabling the MMU

Clear bit 0 (the M bit) in the R1: Control register to disable the MMU.

**Note:** If the MMU is enabled, then disabled, then subsequently re-enabled, the contents of the TLB are preserved. If these are now invalid, the TLB must be invalidated before re-enabling the MMU (see “R8:TLB Operations register” on page 95).

## TLB structure

The MMU runs a single unified TLB used for both data accesses and instruction fetches. The TLB is divided into two parts:

- An eight-entry fully-associative part used exclusively for holding locked down TLB entries.
- A set-associative part for all other entries.

Whether an entry is placed in the set-associative part or lockdown part of the TLB depends on the state of the TLB Lockdown register when the entry is written into the TLB (see “R10:TLB Lockdown register” on page 99).

When an entry has been written into the lockdown part of the TLB, it can be removed only by being overwritten explicitly or, when the MVA matches the locked down entry, by an MVA-based TLB invalidate operation.

The structure of the set-associative part of the TLB does not form part of the programmer’s model for the ARM926EJ-S processor. No assumptions must be made

about the structure, replacement algorithm, or persistence of entries in the set-associative part — specifically:

- Any entry written into the set-associative part of the TLB can be removed at any time. The set-associative part of the TLB must be considered as a temporary cache of translation/page table information. No reliance must be placed on an entry residing or not residing in the set-associative TLB unless that entry already exists in the lockdown TLB. The set-associative part of the TLB can contain entries that are defined in the page tables but do not correspond to address values that have been accessed since the TLB was invalidated.
- The set-associative part of the TLB must be considered as a cache of the underlying page table, where memory coherency must be maintained at all times. To guarantee coherency if a level one descriptor is modified in main memory, either an invalidate-TLB or Invalidate-TLB-by-entry operation must be used to remove any cached copies of the level one descriptor. This is required regardless of the type of level one descriptor (section, level two page reference, or fault).
- If any of the subpage permissions for a given page are different, each of the subpages are treated separately. To invalidate all entries associated with a page with subpage permissions, four MVA-based invalidate operations are required — one for each subpage.

## Caches and write buffer

The ARM926EJ-S processor includes an instruction cache (ICache), data cache (DCache), and write buffer. The instruction cache is 8 KB in length, and the data cache is 4 KB in length.

### Cache features

- The caches are virtual index, virtual tag, addressed using the modified virtual address (MVA). This avoids cache cleaning and/or invalidating on context switch.
- The caches are four-way set associative, with a cache line length of eight words per line (32 bytes per line), and with two dirty bits in the DCache.
- The DCache supports write-through and write-back (copyback) cache operations, selected by memory region using the C and B bits in the MMU translation tables.
- The caches support *allocate on read-miss*. The caches perform critical-word first cache refilling.

- The caches use pseudo-random or round-robin replacement, selected by the RR bit in R1: Control register.
- Cache lockdown registers enable control over which cache ways are used for allocation on a linefill, providing a mechanism for both lockdown and controlling cache pollution.
- The DCache stores the *Physical Address Tag* (PA tag) corresponding to each DCache entry in the tag RAM for use during cache line write-backs, in addition to the virtual address tag stored in the tag RAM. This means that the MMU is not involved in DCache write-back operations, which removes the possibility of TLB misses to the write-back address.
- Cache maintenance operations provide efficient invalidation of:
  - The entire DCache or ICache
  - Regions of the DCache or ICache
  - Regions of virtual memory

Cache maintenance operations also provide for efficient cleaning and invalidation of:

- The entire DCache
- Regions of the DCache
- Regions of virtual memory

The latter allows DCache coherency to be efficiently maintained when small code changes occur; for example, for self-modifying code and changes to exception vectors.

## Write buffer

The write buffer is used for all writes to a noncachable bufferable region, write-through region, and write misses to a write-back region. A separate buffer is incorporated in the DCache for holding write-back data for cache line evictions or cleaning of dirty cache lines.

- The main write buffer has a 16-word data buffer and a four-address buffer.
- The DCache write-back buffer has eight data word entries and a single address entry.

The MCR drain write buffer instruction enables both write buffers to be drained under software control.

The MCR wait -for-interrupt causes both write buffers to be drained, and the ARM926EJ-S processor to be put into low-power state until an interrupt occurs.

## Enabling the caches

On reset, the ICache and DCache entries all are invalidated and the caches disabled. The caches are not accessed for reads or writes. The caches are enabled using the I, C, and M bits from the R1: Control register, and can be enabled independently of one another.

## ICache I and M bit settings

This table gives the I and M bit settings for the ICache, and the associated behavior.

R1 I bit	R1 M bit	ARM926EJ-S behavior
0	-----	ICache disabled. All instruction fetches are fetched from external memory (AHB).
1	0	ICache enabled, MMU disabled. All instruction fetches are cachable, with no protection checks. All addresses are flat-mapped; that is, VA=MVA=PA.
1	1	ICache enabled, MMU enabled. Instruction fetches are cachable or noncachable, depending on the page descriptor C bit (see “ICache page table C bit settings” on page 127), and protection checks are performed. All addresses are remapped from VA to PA, depending on the page entry; that is, the VA is translated to MVA and the MVA is remapped to a PA.

## ICache page table C bit settings

This table shows the page table C bit settings for the ICache (R1 I bit = M bit = 1).

Page table C bit	Description	ARM926EJ-S behavior
0	Noncachable	ICache disabled. All instruction fetches are fetched from external memory.
1	Cachable	<b>Cache hit</b> Read from the ICache. <b>Cache miss</b> Linefill from external memory.

## R1 register C and M bits for DCache

This table gives the R1: Control register C and M bit settings for DCache, and the associated behavior.

R1 C bit	R1 M bit	ARM926EJ-S behavior
0	0	DCache disabled. All data accesses are to the external memory.
1	0	DCache enabled, MMU disabled. All data accesses are noncachable, nonbufferable, with no protection checks. All addresses are flat-mapped; that is, VA=MVA=PA.
1	1	DCache enabled, MMU enabled. All data accesses are cachable or noncachable, depending on the page descriptor C bit and B bit (see “DCache page table C and B settings” on page 127), and protection checks are performed. All addresses are remapped from VA to PA, depending on the MMU page table entry; that is, the VA is translated to an MVA and the MVA is remapped to a PA.

## DCache page table C and B settings

This table gives the page table C and B bit settings for the DCache (R1: Control register C bit = M bit = 1), and the associated behavior.

Page table C bit	Page table B bit	Description	ARM926EJ-S behavior
0	0	Noncachable, nonbufferable	DCache disabled. Read from external memory. Write as a nonbuffered store(s) to external memory. DCache is not updated.
0	1	Noncachable, bufferable	DCache disabled. Read from external memory. Write as a buffered store(s) to external memory. DCache is not updated.
1	0	Write-through	DCache enabled: <b>Read hit</b> Read from DCache. <b>Read miss</b> Linefill. <b>Write hit</b> Write to the DCache, and buffered store to external memory. <b>Write miss</b> Buffered store to external memory.
1	1	Write-back	DCache enabled: <b>Read hit</b> Read from DCache. <b>Read miss</b> Linefill. <b>Write hit</b> Write to the DCache only. <b>Write miss</b> Buffered store to external memory.

## Cache MVA and Set/Way formats

This section shows how the MVA and set/way formats of ARM926EJ-S caches map to a generic virtually indexed, virtually addressed cache, shown next. The next figure shows a generic, virtually indexed, virtually addressed cache.

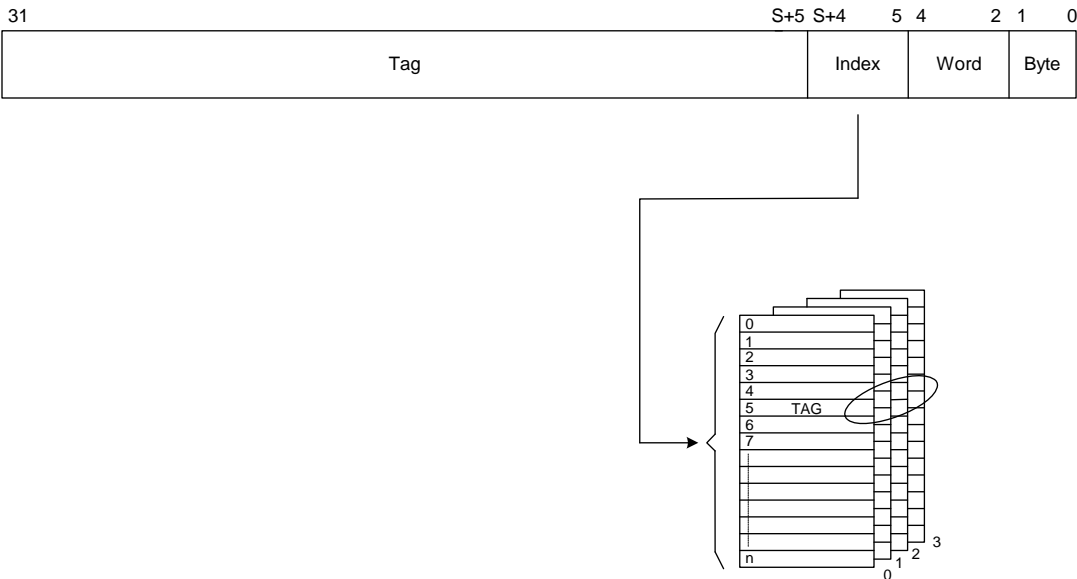

Generic, virtually indexed, virtually addressed cache

ARM926EJ-S  
cache format

ARM926EJ-S  
cache  
associativity

The following points apply to the ARM926EJ-S cache associativity:

- The group of tags of the same index defines a *set*.
- The number of tags in a set is the *associativity*.
- The ARM926EJ-S caches are 4-way associative.
- The range of tags addressed by the index defines a *way*.
- The number of tags in a way is the number of sets, *NSETS*.

This table shows values of S and NSETS for an ARM926EJ-S cache.

ARM926EJ-S	S	NSETS
4 KB	5	32
8 KB	6	64
16 KB	7	128
32 KB	8	256
64 KB	9	512
128 KB	10	1024

Set/way/word  
format for  
ARM926EJ-S  
caches

In this figure:

$$A = \log_2 \text{ associativity}$$

For example, with a 4-way cache  $A = 2$ :

$$S = \log_2 \text{ NSETS}$$

## Noncachable instruction fetches

The ARM926EJ-S processor performs speculative noncachable instruction fetches to increase performance. Speculative instruction fetching is enabled at reset.

**Note:** It is recommended that you use ICache rather than noncachable code, when possible. Noncachable code previously has been used for operating system boot loaders and for preventing cache pollution. ICache, however, can be enabled without the MMU being enabled, and cache pollution can be controlled using the cache lockdown register.

### Self-modifying code

A four-word buffer holds speculatively fetched instructions. Only sequential instructions are fetched speculatively; if the ARM926EJ-S issues a nonsequential instruction fetch, the contents of the buffer are discarded (flushed). In situations on which the contents of the prefetch buffer might become invalid during a sequence of sequential instruction fetches by the processor core (for example, turning the MMU on or off, or turning on the ICache), the prefetch buffer also is flushed. This avoids the necessity of performing an explicit *Instruction Memory Barrier* (IMB) operation, except when self-modifying code is used. Because the prefetch buffer is flushed when the ARM926EJ-S core issues a nonsequential instruction fetch, a branch instruction (or equivalent) can be used to implement the required IMB behavior, as shown in this code sequence:

```
LDMIA    R0,{R1-R5}           ; load code sequence into R1-R5
ADR      R0,self_mod_code
STMIA    R0,{R1-R5}           ; store code sequence (nonbuffered region)
B        self_mod_code         ; branch to modified code
self_mod_code:
```

This IMB application applies only to the ARM926EJ-S processor running code from a noncachable region of memory. If code is run from a cachable region of memory, or a different device is used, a different IMB implementation is required. IMBs are discussed in "Instruction Memory Barrier," beginning on page 132.

**AHB behavior**

If instruction prefetching is disabled, all instruction fetches appear on the AHB interface as single, nonsequential fetches.

If prefetching is enabled, instruction fetches appear either as bursts of four instructions or as single, nonsequential fetches. No speculative instruction fetching is done across a 1 KB boundary.

All instruction fetches, including those made in Thumb state, are word transfers (32 bits). In Thumb state, a single-word instruction fetch reads two Thumb instructions and a four-word burst reads eight instructions.

**Instruction  
Memory Barrier**

Whenever code is treated as data — for example, self-modifying code or loading code into memory — a sequence of instructions called an *instruction memory barrier (IMB)* operation must be used to ensure consistency between the data and instruction streams processed by the ARM926EJ-S processor.

Usually the instruction and data streams are considered to be completely independent by the ARM926EJ-S processor memory system, and any changes in the data side are not automatically reflected in the instruction side. For example, if code is modified in main memory, ICache may contain stale entries. To remove these stale entries, part of all of the ICache must be invalidated.

**IMB operation**

Use this procedure to ensure consistency between data and instruction sides:

- 1 **Clean the DCache.** If the cache contains cache lines corresponding to write-back regions of memory, it might contain dirty entries. These entries must be cleaned to make external memory consistent with the DCache. If only a small part of the cache has to be cleaned, it can be done by using a sequence of clean DCache single entry instructions. If the entire cache has to be cleaned, you can use the test and clean operation (see "R7:Cache Operations register," beginning on page 92).
- 2 **Drain the write buffer.** Executing a drain write buffer causes the ARM926EJ-S core to wait until outstanding buffered writes have completed on the AHB interface. This includes writes that occur as a result of data being written back to main memory because of clean operations, and data for store instructions.
- 3 **Synchronize data and instruction streams in level two AHB systems.** The level two AHB subsystem might require synchronization between data and instruction sides. It is possible for the data and instruction AHB masters to be attached to different AHB subsystems. Even if both masters are present on the same bus, some form of separate ICache might exist for performance reasons; this must be invalidated to ensure consistency.

The process of synchronizing instructions and data in level two memory must be invoked using some form of fully blocking operation, to ensure that the end of the operation can be determined using software. It is

recommended that either a nonbuffered store (STR) or a noncached load (LDR) be used to trigger external synchronization.

- 4 **Invalidate the cache.** The ICache must be invalidated to remove any stale copies of instructions that are no longer valid. If the ICache is not being used, or the modified regions are not in cachable areas of memory, this step might not be required.
- 5 **Flush the prefetch buffer.** To ensure consistency, the prefetch buffer should be flushed before self-modifying code is executed (see "Self-modifying code" on page 131).

### Sample IMB sequences

These sequences correspond to steps 1-4 in "IMB operation."

clean loop

```

MRC p15, 0, r15, c7, c10, 3      ; clean entire dcache using test and clean
BNE clean_loop

MRC p15, 0, r0, c7, c10, 4      ; drain write buffer
STR rx,[ry]                     ; nonbuffered store to signal L2 world to
                                ; synchronize
MCR p15, 0, r0, c7, c5, 0       ; invalidate icache

```

This next sequence illustrates an IMB sequence used after modifying a single instruction (for example, setting a software breakpoint), with no external synchronization required:

```

STR rx,[ry]                     ; store that modifies instruction at address ry
MCR p15, 0, ry, c7, c10, 1      ; clean dcache single entry (MVA)
MCR p15, 0, r0, c7, c10, 4      ; drain write buffer
MCR p15, 0, ry, c7, c5, 1       ; invalidate icache single entry (MVA)

```

# System Control Module

## C H A P T E R 4

The System Control Module configures and oversees system operations for the processor, and defines both the AMBA High-speed Bus (AHB) arbiter system and system memory address space.

### Features

The System Control Module uses the following to configure and maintain system operations:

- AHB arbiter system
- System-level address decoding
- 11 programmable timers
  - Watchdog timer
  - 10 general purpose timers/counters
- Interrupt controller
- Multiple configuration and status registers
- System Sleep/Wake-up processor

### Bus interconnection

The AMBA AHB bus protocol uses a central multiplexor interconnection scheme. All bus masters generate the address and control signals that indicate the transfer that the bus masters want to perform. The arbiter determines which master has its address and control signals routed to all slaves. A central decoder is required to control the read data and response multiplexor, which selects the appropriate signals from the slave that is involved in the transfer.

### System bus arbiter

The bus arbitration mechanism ensures that only one bus master has access to the system bus at any time. If you are using a system in which bus bandwidth allocation is critical, you must be sure that your worst-case bus bandwidth allocation goals can

be met. See “Arbiter configuration example” on page 140 for information about configuring the AHB arbiter.

### High speed bus system

The high-speed bus system is split into two subsystems:

- **High-speed peripheral subsystem:** Connects all high-speed peripheral devices to a port on the external memory controller.
- **CPU subsystem:** Connects the CPU directly to a second port on the external memory controller.

### High-speed bus arbiters

The high-speed bus contains two arbiters: one for the ARM926 (CPU) and one for the main bus.

- **CPU arbiter.** Splits the bandwidth 50-50 between the data and instruction interfaces. If the CPU access is to external memory, no further arbitration is necessary; the CPU has immediate access to external memory through slave port 0 on the memory controller. If CPU access is to one of the peripherals on the main bus, however, the main arbiter will arbitrate the access.
- **Main arbiter.** Contains a 16-entry Bus Request Configuration (BRC) register. Each BRC entry represents a bus request and grant channel. Each request/grant channel can be assigned to only one bus master at a time. Each bus master can be connected to multiple request/grant channels simultaneously, however, depending on the bus bandwidth requirement of that master.

Each request/grant channel has a two-bit Bandwidth Reduction Field (BRF) to determine how often each channel can arbitrate for the system bus — 100%, 75%, 50%, or 25%. A BRF value of 25%, for example, causes a channel to be skipped every 3 or 4 cycles. The BRC gates the bus requesting signals going into a 16-entry Bus Request register (BRR). As a default, unassigned channels in the BRC block the corresponding BRR entries from being set by any bus request signals. On powerup, only the CPU is assigned to one of the channels with 100% bandwidth strength as the default setting.

### How the bus arbiter works

- 1 The arbiter evaluates the BRR at every bus clock until one or more bus requests are registered.
- 2 The arbiter stops evaluating the BRR until a bus grant is issued for the previous evaluation cycle.
- 3 The arbiter grants the bus to requesting channels, in a round-robin manner, at the rising clock edge of the last address issued for the current transaction (note

that each transaction may have multiple transfers), when a SPLIT response is sampled by the arbiter, or when the bus is idling.

- 4 Each master samples the bus grant signal (`hgrant_x`) at the end of the current transfer, as indicated by the `hready` signal. The bus master takes ownership of the bus at this time.
- 5 The arbiter updates the `hmaster [3:0]` signals at the same time to indicate the current bus master and to enable the new master's address and control signals to the system bus.

See your AMBA standards documentation for detailed information and illustrations of AMBA AHB transactions.

### Ownership

Ownership of the data bus is delayed from ownership of the address/control bus. When `hready` indicates that a transfer is complete, the master that owns the address/control bus can use the data bus — and continues to own that data bus — until the transaction completes.

**Note:** If a master is assigned more than one request/grant channel, these channels need to be set and reset simultaneously to guarantee that a non-requesting master will not occupy the system bus.

### Locked bus sequence

The arbiter observes the `hlock_x` signal from each master to allow guaranteed back-to-back cycles, such as read-modified-write cycles. The arbiter ensures that no other bus masters are granted the bus until the locked sequence has completed. To support SPLIT or RETRY transfers in a locked sequence, the arbiter retains the bus master as granted for an additional transfer to ensure that the last transfer in the locked sequence completed successfully.

If the master is performing a locked transfer and the slave issues a split response, the master continues to be granted the bus until the slave finishes the SPLIT response. (This situation degrades AHB performance.)

### Relinquishing the bus

When the current bus master relinquishes the bus, ownership is granted to the next requester.

- If there are no new requesters, ownership is granted to the last master.
- Bus parking must be maintained if other masters are waiting for SPLIT transfers to complete.
- If the bus is granted to a default master and continues to be in the IDLE state longer than a specified period of time, an AHB bus arbiter timeout is generated. An AHB bus arbiter timeout can be configured to interrupt the CPU or to reset the chip.

**SPLIT transfers**

A SPLIT transfer occurs when a slave is not ready to perform the transfer. The slave splits, or masks, its master, taking away the master's bus ownership and allowing other masters to perform transactions until the slave has the appropriate resources to perform its master's transaction.

The bus arbiter supports SPLIT transfers. When a SPLIT response is issued by a slave, the current master is masked for further bus requesting until a corresponding `hsplit_x[15:0]` signal is issued by the slave indicating that the slave is ready to complete the transfer. The arbiter uses the `hsplit_x[15:0]` signals to unmask the corresponding master, and treats the master as the highest-priority requester for the immediate next round of arbitration. The master eventually is granted access to the bus to try the transfer again.

**Note:** The arbiter automatically blocks bus requests with addresses directed at a "SPLITting" slave until that SPLIT transaction is completed.

**Arbiter configuration example**

This example shows how to configure the AHB arbiter to guarantee bandwidth to a given master. These are the conditions in this example:

- 5 AHB masters — CPU, Ethernet Rx, Ethernet Tx, IO hub, and external DMA
- AHB clock frequency — 75 MHz
- Average access time per 16-byte memory access — 4 clock cycles
- The ARM926EJ-S is guaranteed one-half the total memory bandwidth

In this example, the bandwidth for each master can be calculated using this formula:

Bandwidth per master:

$$= [(75\text{MHz}/2) / (4 \text{ clock cycles per access} \times 5 \text{ masters})] \times 16 \text{ bytes}$$

$$= 60\text{MB/master}$$

**Note:** The worst case scenario is that there are 90 Mbps total to be split by all 5 masters.

if this meets the requirements of all the masters, the AHB arbiter is programmed like this:

BRC0[31:24]	= 8'b1_0_00_0000	channel enabled, 100%, ARM7EJ-S
BRC0[23:16]	= 8'b1_0_00_0001	channel enabled, 100%, Ethernet Rx
BRC0[15:8]	= 8'b1_0_00_0000	channel enabled, 100%, Ethernet TX
BRC0[7:0]	= 8'b1_0_00_0101	channel enabled, 100%, IO hub
BRC1[31:24]	= 8'b1_0_00_0011	channel enabled, 100%, Ext DMA
BRC1[23:16]	= 8'b1_0_00_0000	channel disabled
BRC1[15:8]	= 8'b1_0_00_0000	channel disabled
BRC1[7:0]	= 8'b1_0_00_0000	channel disabled
BRC2[31:24]	= 8'b0_0_00_0000	channel disabled
BRC2[23:16]	= 8'b0_0_00_0000	channel disabled

BRC2[15:8]	= 8'b0_0_00_0000	channel disabled
BRC2[7:0]	= 8'b0_0_00_0000	channel disabled
BRC3[31:24]	= 8'b0_0_00_0000	channel disabled
BRC3[23:16]	= 8'b0_0_00_0000	channel disabled
BRC3[15:8]	= 8'b0_0_00_0000	channel disabled
BRC3[7:0]	= 8'b0_0_00_0000	channel disabled

## Address decoding

A central address decoder provides a select signal — `hsel_x` — for each slave on the bus.

This table shows how the system memory address is set up to allow access to the internal and external resources on the system bus. Note that the external memory chip select ranges can be reset after powerup. The table shows the default powerup values; you can change the ranges by writing to the BASE and MASK registers.

See “Memory Controller” on page 201” for boot sequences.

See “System Memory Chip Select 0 Dynamic Memory Base and Mask registers” on page 190” through “System Memory Chip Select 3 Dynamic Memory Base and Mask registers” on page 192 for more information.

Address range	Size	System functions
Dynamic Chip selects		
0x0000 0000 – 0x0FFF FFFF	256 MB	cs[1] Chip select 1, default - dy_cs0 (boot to SDRAM)
0x1000 0000 – 0x1FFF FFFF	256 MB	cs[3] Chip select 3, default - dy_cs1
0x2000 0000 – 0x2FFF FFFF	256 MB	cs[5] Chip select 5, default - dy_cs2
0x3000 0000 – 0x3FFF FFFF	256 MB	cs[7] Chip select 7, default - dy_cs3
Static Chip Selects		
0x4000 0000 – 0x4FFF FFFF	256 MB	cs[0] Chip select 0, default - st_cs0 (or boot to SRAM)
0x5000 0000 – 0x5FFF FFFF	256 MB	cs[2] Chip select 2, default - st_cs1 (boot from Flash)
0x6000 0000 – 0x6FFF FFFF	256 MB	cs[4] Chip select 4, default - st_cs2
0x7000 0000 – 0x7FFF FFFF	256 MB	cs[6] Chip select 6, default - st_cs3
0x8000 0000 – 0x8FFF FFFF	256 MB	Reserved
0x9000 0000 – 0x9FFF FFFF	256 MB	IO hub
0xA000 0000 – 0xA05F FFFF	6 MB	Reserved
0xA060 0000 – 0xA06F FFFF	1 MB	Ethernet Communication Module

Address range	Size	System functions
0xA070 0000 – 0xA07F FFFF	1 MB	Memory controller
0xA080 0000 – 0xA08F FFFF	1 MB	External DMA module
0xA090 0000 – 0xA09F FFFF	1 MB	System Control Module
0xA0A0 0000 – 0xFFFF FFFF	1526MB	Reserved

The Hardware Reference Manual uses different internal names when describing the chip selects. Below are the chip select hardware reference manual internal names.

NS9215 pin name	Internal name	Memory boot use
cs[0] Chip select 0, default - st_cs0	chip select 0	boot to SRAM
cs[2] Chip select 2, default - st_cs1	chip select 1	boot to flash
cs[4] Chip select 4, default - st_cs2	chip select 2	
cs[6] Chip select 6, default - st_cs3	chip select 3	
cs[1] Chip select 1, default - dy_cs0	chip select 4	boot to SDRAM
cs[3] Chip select 3, default - dy_cs1	chip select 5	
cs[5] Chip select 5, default - dy_cs2	chip select 6	
cs[7] Chip select 7, default - dy_cs3	chip select 7	
These are the default settings. All of the chip select pins are re-programmable		

This table shows the hmaster[3:0] assignments for the processor.

Master Name	hmaster[3:0] assignment
ARM926 data	0000
Ethernet Rx	0001
Ethernet Tx	0010
IO hub	0100
ARM926 instruction	0101

## Programmable timers

The processor provides 11 programmable timers:

- Software watchdog timer
- 10 general purpose timers

**Software  
watchdog timer**

The software watchdog timer, set to specific time intervals, handles gross system misbehaviors. The watchdog timer can be set to timeout in longer ranges of time intervals, typically in seconds.

The software watchdog timer can be enabled or disabled, depending on the operating condition. When enabled, system software must write to the Software Watchdog Timer register before it expires. When the timer does timeout, the system is preconfigured to generate an IRQ, an FIQ, or a RESET to restart the entire system.

**General purpose timers/counters**

Ten 32-bit general purpose timers/counters (GPTC) provide programmable time intervals to the CPU when used as one or multiple timers. There are two I/O pins associated with each timer.

- When used as a *gated* timer, one I/O pin serves as an input qualifier (high/low programmable).
- When used as a *regular* timer (enabled by software), the other I/O pin serves as a terminal count indicator output.

These pins can also be used independently as up/down counters to monitor the frequency of certain events (events capturing). In this situation, the I/O pin becomes the clock source of the counter.

**Source clock  
frequency**

Depending on the applications, the source clock frequency of the timers/counters is selectable among the system memory clock, the system memory clock with multiple divisor options, or an external pulse event. The divisor options are 2, 4, 8, 16, 32, 64, 128, or 256. If an external pulse is used, the frequency must be less than one half the system memory clock frequency.

**GPTC  
characteristics**

- Each GPTC can measure external event lengths up to minutes range, and can be individually enabled/disabled.
- Each GPTC can be configured to reload, with the value defined in the Initial Timer Count register (one for each GPTC), and generates an interrupt upon terminal count.
- Each GPTC has an interrupt request connected to the IRQ interrupt controller (VIC). The priority level and enable/disable of each interrupt can be programmed in the VIC. The CPU can read the contents of the timer/counter.
- GPTCs can be concatenated to form larger timer counters.

**Control field**

Include this control field in each of the 32-bit timer/counter control registers:

- Clock frequency selection
- Mode of operation:
  - Internal timer, with or without external terminal count indicator
  - External gated timer with gate active low
  - External gated timer with gate active high
  - External event counter — frequency must be less than one half the system memory clock frequency
- Timer/counter enable
- Count up or down
- Interrupt enable
- Concatenate to up-stream timer/counter; that is, use up-stream timer/counter's overflow/underflow output as clock input
- Reload enable
- Basic PWM function
- Enhanced PWM functionality (timers 6-9)
- Quadrature decoder function (timer 5)
- 32-bit or 16-bit operation

**16-bit mode options**

These options are available in 16-bit mode:

- **Capture mode.** Capture the counter value on the rising or falling edge of an external event and interrupt the CPU.
- **Compare mode.** Interrupt the CPU when the counter value is equal to the Match register.

**Basic PWM function**

Any of the timer/counters can be configured to provide a basic PWM function. Each PWM function requires concatenating two timer/counters, resulting in five PWM outputs. One of the timer/counters controls the pulse width and the other controls the period. The basic PWM function is output through GPIO through functions labeled PWM Ch *N*.

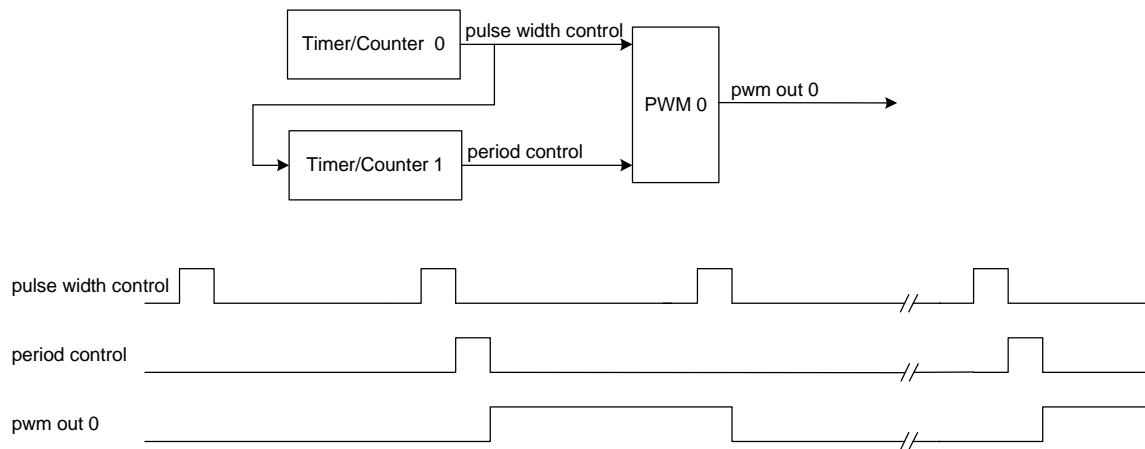

PWM Channel	gpio number	Package Pin number
PWM Ch 0	gpio [70]	N10
PWM Ch 1	gpio [71]	P11

PWM Channel	gpio number	Package Pin number
PWM Ch 2	gpio [72]	N12
PWM Ch 3	gpio [73]	R13
PWM Ch 4	gpio [100]	D8

### Functional block diagram

This diagram illustrates the basic PWM function:

### Enhanced PWM function

Timer counters 6-9 have additional features to add enhanced PWM functionality:

- High register – Compared to the timer/counter to toggle PWM output high
- Low register – Compared to the timer/counter to toggle PWM output back low
- Three 15-bit Step registers associated with four enhanced timer/counters. The values of Step registers are added when the high, low, and reload values are reached, which allows a steadily variable motor control PWM wave to be generated. The enhanced PWM function is output through GPIO through the functions labeled Ext Timer Event Out Ch N for channels 6 to 9.

EXT Timer Event Out Channel	gpio number	Package Pin number
EXT Timer Event Out Ch 6	gpio [5] or gpio [90]	H13 or H16
EXT Timer Event Out Ch 7	gpio [7] or gpio [91]	G14 or H15
EXT Timer Event Out Ch 8	gpio [8] or gpio [92]	G17 or F14

EXT Timer Event Out Channel	gpio number	Package Pin number
EXT Timer Event Out Ch 9	gpio [13] or gpio [93]	F15 or F16

### Sample enhanced PWM waveform

## Quadrature decoder function

The processor provides a quadrature decoder function to allow the CPU to determine the external device rate of rotation and the direction of rotation. Example applications are robotic axles for feedback control, mechanical knobs to determine user input, and in computer mice, to determine direction of movement.

Timer/counter five includes a quadrature decoder function, which takes some computational load off the CPU. When a CPU reads the output signals of a quadrature encoder, every state must be decoded and a counter needs to be updated based on the interpretation of the states. For example, for an encoder of 256 pulses per revolution turning at a modest 6000 rpm, the CPU needs to find and decoded 102,400 state changes per second and update the counter accordingly. With an x8 sampling rate, the CPU needs to sample the input about 8 x 102,400 timer per second. This consumes a significant portion of the CPU bandwidth.

A quadrature decoder/counter module performs these tasks at real time speed and interrupts the CPU at the predetermined conditions.

## How the quadrature decoder/counter works

### Provides input signals

A quadrature encoder provides a pair of signals (in-phase and quad-phase) with opposite polarities and a 90-degree phase shift. Decode these signals to create an algorithm to determine the direction, speed, and position of a motion wheel.

### Input signals

**Quadrature encoding truth table****Legend:**

NC — No change

CW — Clockwise

CCW — Counter clockwise

Err — Error

		New State			
		I:Q	00	01	10
Current State	00	NC	CW	CCW	Err
	01	CCW	NC	Err	CW
	10	CW	Err	NC	CCW
	11	Err	CCW	CW	NC

**Monitors how far the encoder has moved**

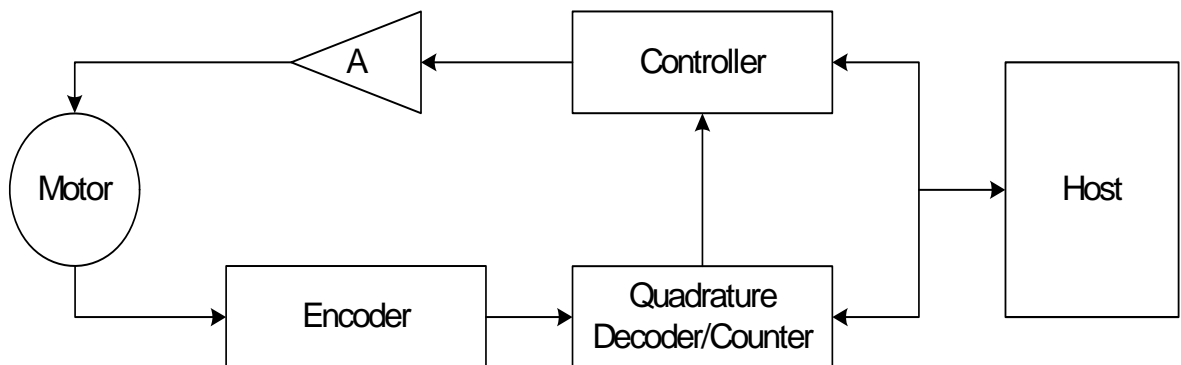

The counter keeps a running count of how far the encoder has moved.

- The decoder increments a 32-bit counter when a state change is found in the positive (CW) direction.
- The decoder decrements a 32-bit counter when a state change is found in the other (CCW) direction.

When the programmed number reaches the terminal count, the counter is reset and an interrupt is generated to the CPU. The CPU can also read the counter directly to sense the direction of the motor.

**Typical application**

This diagram shows a typical application of the quadrature decoder/counter:

**Digital filter**

To ensure the precision and quality of the quadrature decoder/counter, a digital filter rejects noise on the incoming quadrature signals using three-clock-cycle delayed filtering. The three-clock-cycle delay filter rejects large and short duration noise spikes that typically occur in motor system applications.

**Testing signals**

Each signal is sampled on rising clock edges. A time history of the signals is stored in a four-bit shift register. Any signal is tested for a stable level that is present for three consecutive rising clock edges. With this method, pulses shorter than a two-clock period are rejected.

**Timer support**

Timer counter 5 supports the sampling clock and the counters.

## Interrupt controller

The interrupt system is a simple two-tier priority scheme. Two lines access the CPU core and can interrupt the processor: IRQ (normal interrupt) and FIQ (fast interrupt). FIQ has a higher priority than IRQ.

**FIQ interrupts**

Most sources of interrupts on the processor are from the IRQ line. There is only one FIQ source for timing-critical applications. The FIQ interrupt generally is reserved for timing-critical applications for these reasons:

- The interrupt service routine is executed directly without determining the source of the interrupt.
- Interrupt latency is reduced. The banked registers available for FIQ interrupts are more efficient because a context save is not required.

**Note:** The interrupt source assigned to the FIQ must be assigned to the highest priority, which is 0.

**IRQ interrupts**

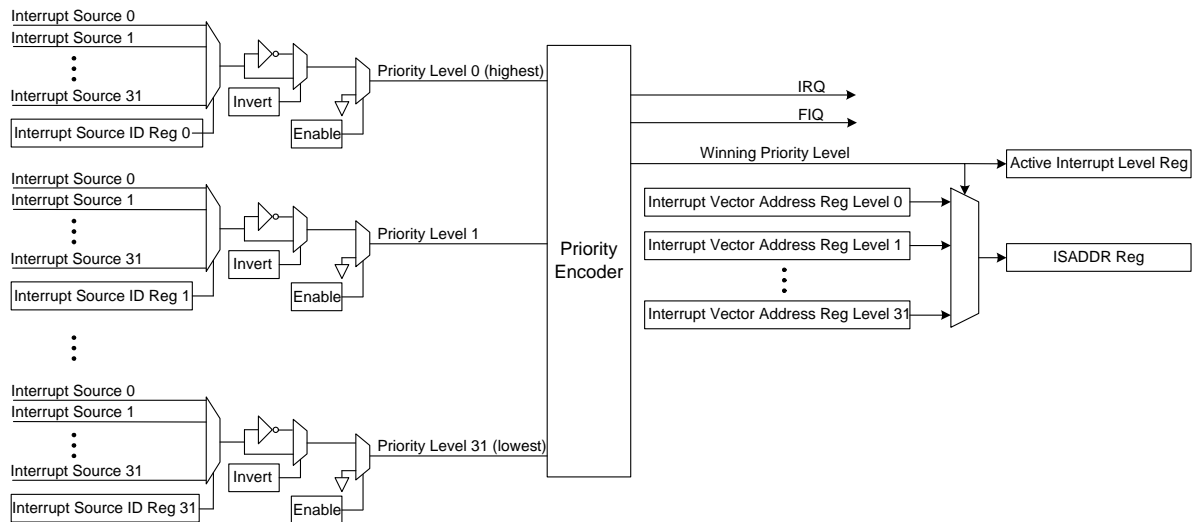

IRQ interrupts come from several different sources in the processor and are managed using the Interrupt Config registers (see “Int (Interrupt) Config (Configuration) 31-0 registers” on page 175). IRQ interrupts can be enabled or disabled on a per-level basis using the Interrupt Enable registers. These registers serve as masks for the different interrupt levels. Each interrupt level has two registers:

- **Interrupt Configuration register.** Use this register to assign the source for each interrupt level, invert the source polarity, select IRQ or FIQ, and enable the level.
- **Interrupt Vector Address register.** Contains the address of the interrupt service routine.

### 32-vector interrupt controller

The next figure shows a 32-vector interrupt controller:

### IRQ characteristics

- The IRQ interrupts are enabled by the respective enabling bits.
- Once enabled, the interrupt source programmed in the Interrupt Configuration register for each priority level connects the interrupt to one of 32 priority lines going into the priority encoder block.
- The priority encoder block has a fixed order, with line 0 as the highest priority. The interrupt with the highest priority level has its encoded priority level displayed, to select the appropriate vector for the ISADDR register (see “ISADDR register” on page 176).
- The CPU, once interrupted, can read the ISADDR register to get the address of the Interrupt Service Routine. A read to the ISADDR register updates the priority encoder block, which masks the current and any lower priority interrupt requests. Writing to this address indicates to the priority hardware that the current interrupt is serviced, allowing lower priority interrupts to become active.
- The write value to the ISADDR register must be the level of the interrupt being serviced. Valid values are 0–31.
- The priority encoder block enables 32 prioritized interrupts to be serviced in nested fashion. A software interrupt can be implemented by writing to a software interrupt register. The software interrupt typically is assigned level 1 or level 2 priority.

### Interrupt sources

An Interrupt Status register shows the current active interrupt requests. The Raw Interrupts register shows the status of the unmasked interrupt requests.

The interrupt sources are assigned as shown:

Interrupt ID	Interrupt source
0	Watchdog Timer
1	AHB Bus Error
2	Ext DMA
3	CPU Wake Interrupt
4	Ethernet Module Receive Interrupt
5	Ethernet Module Transmit Interrupt
6	Ethernet Phy Interrupt
7	UART A Interrupt
8	UART B Interrupt
9	UART C Interrupt
10	UART D Interrupt
11	SPI Interrupt
12	Reserved
13	Reserved
14	ADC Interrupt
15	Early Power Loss Interrupt
16	I <sup>2</sup> C Interrupt
17	RTC Interrupt
18	Timer Interrupt 0
19	Timer Interrupt 1
20	Timer Interrupt 2
21	Timer Interrupt 3
22	Timer Interrupt 4
23	Timer Interrupt 5
24	Timer Interrupt 6
25	Timer Interrupt 7
26	Timer Interrupt 8
27	Timer Interrupt 9
28	External Interrupt 0
29	External Interrupt 1
30	External Interrupt 2
31	External Interrupt 3

## Vectored interrupt controller (VIC) flow

This is how the VIC flow works:

- 1 An interrupt occurs.
- 2 The CPU branches to either the IRQ or FIQ interrupt vector.
- 3 If the CPU goes to the IRQ vector, the CPU reads the service routine address from the VIC's ISADDR register. The READ updates the VIC's priority hardware to prevent current or any lower priority interrupts from interrupting again. The CPU must not read the ISADDR register for FIQ interrupts.
- 4 The CPU branches to the Interrupt Service Routine (ISR) and stacks the workspace so the IRQ can be enabled.
- 5 The CPU enables the IRQ interrupts so higher priority interrupts can be serviced.
- 6 The CPU executes the interrupt service routine.
- 7 The CPU clears the source of the current interrupt.
- 8 The CPU disables the IRQ and restores the workspace.
- 9 If IRQ, the CPU writes the level value of the interrupt being serviced to the ISADDR register to clear the current interrupt path in the VIC's priority hardware.
- 10 The CPU returns from the interrupt.

## Configurable system attributes

System software can configure these system attributes:

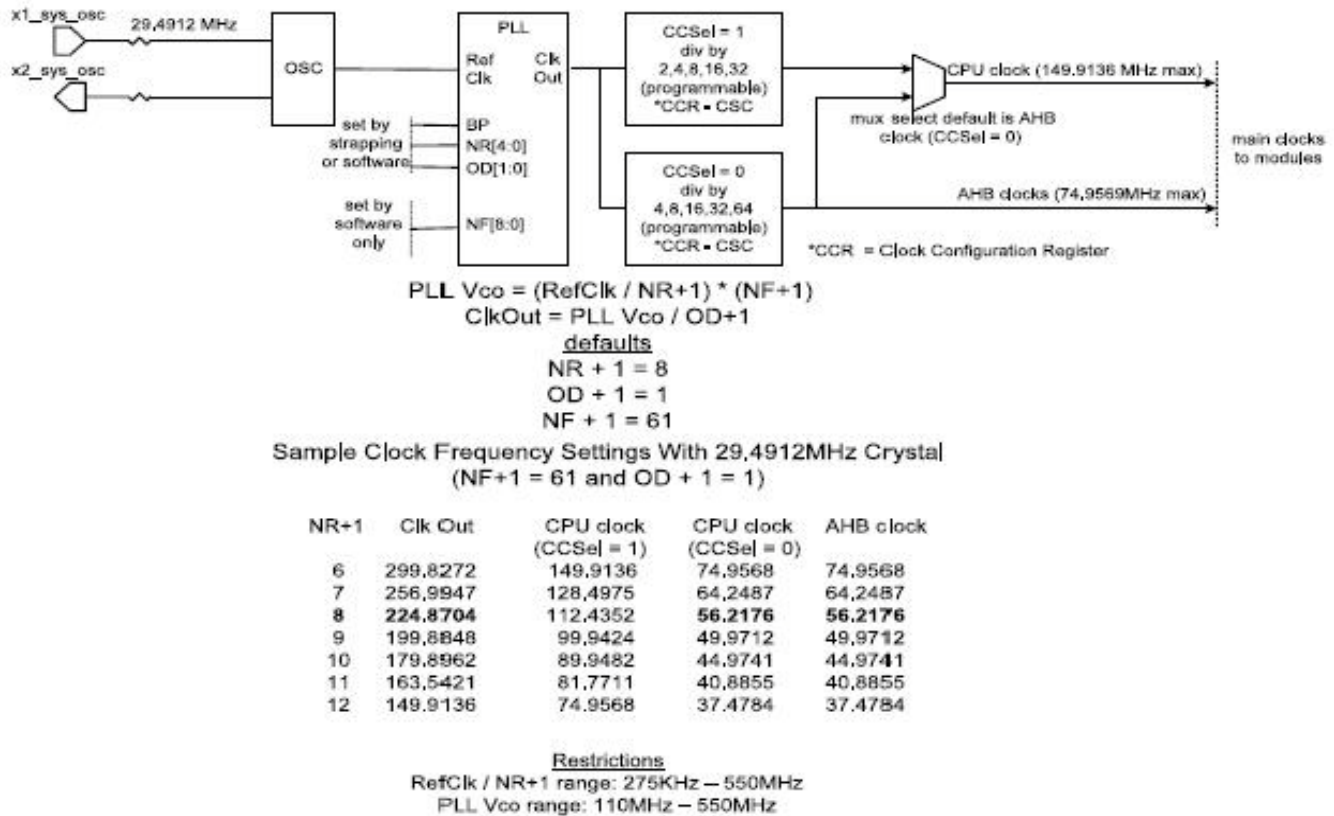

- Little endian/big endian mode
- Watchdog timer enable
- Watchdog timeout generates IRQ/FIQ/RESET
- Watchdog timeout interval
- Enable/disable ERROR response for misaligned data access
- System module clock enables
- Enable access to internal registers in USER mode

## PLL configuration

Hardware strapping determines the initial powerup PLL (see "Bootstrap initialization" on page 152). After powerup, software can change the PLL settings by writing to the PLL Configuration register.

## PLL configuration and control system block diagram

## Bootstrap initialization

The PLL and other system configuration settings can be configured at powerup before the CPU boots. External pins configure the necessary control register bits at powerup. There are internal pullup resistors on these pins to provide a default configuration. External pulldown resistors can configure the PLL and system configuration registers depending on the application.

### Configuring the powerup settings

This table shows how each bit configures the powerup settings.

- 0 = Use an external pulldown
- 1 = Use the internal pullup

Pin name	Configuration bits					
gpio_a[3]	Endian configuration					
	0	Little endian				
	1	Big endian				
gpio_a[2]	Boot mode					
	0	Boot from SDRAM using serial SPI EEPROM				
	1	Boot from Flash ROM				
gpio_a[0], addr[23]	Flash/SPI configuration					
	If booting from Flash:					
	00	8 bit				
	01	32 bit				
	10	32 bit				
	11	16 bit				
	If booting from SPI					
	00	Reserved				
	01	8-bit addressing				
	10	24-bit addressing				
	11	16-bit addressing				
addr[19:9]	Gen ID					
addr[7]	PLL bypass setting					
	0	Bypass				
	1	Normal operation				
addr[6:5]	PLL output divider setting OD					
	00	3				
	01	2				
	10	1				
	11	0

## System configuration registers

All configuration registers must be accessed as 32-bit words and as single accesses only. Bursting is not allowed.

## General Arbiter Control register

Address: A090 0000

The General Arbiter Control register controls whether the CPU access is routed through the main arbiter or is connected directly to the memory controller.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reserved															Arb Control

### Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:01	N/A	Reserved	N/A	N/A
D00	R	ArbControl	0x0	<b>Arbiter control</b> 0 CPU connected directly to memory controller 1 CPU connected to main arbiter

## BRC0, BRC1, BRC2, and BRC3 registers

Addresses: A090 0004 / 0008 / 000C / 0010

The BRC[0:3] registers control the AHB arbiter bandwidth allocation scheme.

**Channel allocation**

This is how the channels are assigned in the four registers:

Register name	[31:24]	[23:16]	[15:08]	[07:00]
BRC0	Channel 0	Channel 1	Channel 2	Channel 3
BRC1	Channel 4	Channel 5	Channel 6	Channel 7
BRC2	Channel 8	Channel 9	Channel 10	Channel 11
BRC3	Channel 12	Channel 13	Channel 14	Channel 15

**Register**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Channel 0, 4, 8, or 12								Channel 1, 5, 9, or 13							
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Channel 2, 6, 10, or 14								Channel 3, 7, 11, or 15							
								CEB	Rsvd	BRF	HMSTR				

**Register bit assignment**

This table shows the bit definition for each channel, using data bits [07:00] as the example.

Bits	Access	Mnemonic	Reset	Description
D07	R/W	CEB	0x0	<b>Channel enable bit</b> 0 Disabled 1 Enabled
D06	N/A	Reserved	N/A	N/A
D05:04	R/W	BRF	0x0	Bandwidth reduction field Program the weight for each AHB bus master. Used to limit access to the round robin scheduler. 00 100% 01 75% 10 50% 11 25%
D03:00	R/W	HMSTR	0x0	hmaster Program a particular AHB bus master number here. Note that a particular master can be programmed to more than one channel.

**AHB Error Detect Status 1**

.....

Address: A090 0018

The AHB Error Detect Status 1 register records the `haddr[31:0]` value present when any AHB error is found. Note that this value is not reset on powerup but is reset when the AHB Error Interrupt Clear bit is set in the AHB Error Monitoring Configuration register (\*).

## Register

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:00	*	EDS1	Not reset	The <code>haddr[31:0]</code> value recorded during a slave error response.

## AHB Error Detect Status 2

Address: A090 001C

The AHB Error Detect Status 2 register records AHB master and slave values present when any AHB error is found. This register also records which error condition was triggered. Note that this value is not reset on powerup but is reset when the AHB Interrupt Clear bit is set in the AHB Error Monitoring Configuration register (\*).

## Register

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:20	N/A	Reserved	N/A	N/A
D19	*	IE	Not reset	<b>CPU instruction error</b> An error was found on the CPU instruction access to external memory. The other fields in this register and the AHB Error Status 1 register are not valid if this bit is set.
D18	*	DE	Not reset	<b>CPU data error</b> An error was found on the CPU data access to external memory. The other fields in this register and the AHB Error Status 1 register are not valid if this field is set.
D17	*	ER	Not reset	<b>AHB error response</b> Set if an AHB slave ERROR response is found.
D16:15	N/A	Reserved	N/A	N/A
D14	*	HWR	Not reset	hwrite <b>Transaction type: write or read.</b>
D13:10	*	HMSTR	Not reset	<b>hmaster[3:0]</b> Initiating master identifier.
D09:06	*	HPR	Not reset	<b>hprot[3:0]</b> Transaction protection code.
D05:03	*	HSZ	Not reset	<b>hsize[2:0]</b> Transaction size.
D02:00	*	HBRST	Not reset	hburst[2:0] Transaction burst type

## AHB Error Monitoring Configuration register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## Timer 6–9 High registers

Addresses: A090 0078 / 007C / 0080 / 0084

The Timer 6–9 High registers contains the high registers for the enhanced PWM features available in timers 6 through 9.

Register

Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:00	R/W	High	0x0	The PWM output toggles high when the timer counter reaches this value.

Timer 6-9 Low registers

.....

Addresses: A090 0088 / 008C / 0090 / 0094

The Timer 6-9 Low registers contain the low registers for the enhanced PWM features available in timers 6 through 9.

Register

Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:00	R/W	Low	0x0	The PWM output toggles low when the timer counter reaches this value.

## Timer 6-9 High and Low Step registers

Addresses: A090 0098 / 009C / 00A0 / 00A4

The Timer 6-9 High and Low Step registers contain the high and low step registers for the enhanced PWM features available in timers 6 through 9.

### Register

Lo Step Dir	Lo Step														

### Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31	R/W	Hi Step Dir	0x0	<b>High step direction</b> 0 Subtract the high step value from the original high register value to increase the high time. 1 Add the high step value to the original high register value to decrease the high time.
D30:16	R/W	Hi Step	0x0	<b>High step</b> This value is either added or subtracted from the original high register value once each cycle.
D15	R/W	Lo Step Dir	0x0	<b>Low step direction</b> 0 Subtract the low step value from the original low register value to increase low time 2. 1 Add the low step value to the original low register value to decrease low time 2.
D14:00	R/W	Lo Step	0x0	<b>Low step</b> This value is either added or subtracted from the original low register value once each cycle.

## Timer 6-9 Reload Step registers

Addresses: A090 00A8 / 00AC / 00B0 / 00B4

The Timer 6-9 reload Step registers contain the reload step registers for the enhanced PWM features available in timers 6 through 9.

**Register****Register bit assignment**

Bits	Access	Mnemonic	Reset	Description
D31:16	N/A	Reserved	N/A	N/A
D15	R/W	Rel Dir	0x0	<b>Reload step direction</b> 0 Subtract the reload step value from the original reload register value to increase the overall period. 1 Add the reload step value to the original reload register value to decrease the overall period.
D14:00	R/W	Rel Step	0x0	<b>Reload step</b> This value is either added or subtracted from the original low register value once each cycle.

**Timer 0-9 Reload Count and Compare register**

Addresses: A090 0028 / 002C / 0030 / 0034 / 0038 / 003C / 0040 / 0044 / 0048 / 004C

The Timer 0 to 9 Reload Count and Compare register holds the up/down reload and compare values for timers 0 to 9.

**Register**

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:16	R/W	Comp Rel Cnt	0x0	<b>Timer Compare register or Timer Reload Bits 31:16 Count register</b> An external toggle or pulse is generated each time the timer value matches this value. An interrupt is generated, if enabled. If configured for a 32-bit timer, bits 31:16 timer reload.
D15:00	R/W	Rel 15:0	0x0	<b>Timer Reload Bits 15:00 Count register</b> This value is loaded into the Timer register after the timer is enabled and after the terminal count has been reached if the reload enable bit is set.

## Timer 0-9 Read and Capture register

Addresses: A090 0050 / 0054 / 0058 / 005C / 0060 / 0064 / 0068 / 006C / 0070 / 0074

The Timer 0 to 9 Read and Capture register reads the current state of each timer and capture register.

## Register

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:16	R/W	Cap Read	0x0	<b>Timer Capture register or Timer Read Bits 31:16 register</b> Reads the capture value of each timer. An interrupt is generated on a capture event, if enabled. If configured as a 32-bit timer, then bits 31:16 of the current state of each timer.
D15:00	R/W	Read 15:0	0x0	<b>Timer Read Bits 15:00 register</b> Reads bits 15:00 of the current state of each timer.

## Interrupt Vector Address Register Level 31-0

Addresses: A090 00C4 (level 0) / 00C8 / 00CC / 00D0 / 00D4 / 00D8 / 00DC / 00E0 / 00E4 / 00E8 / 00EC / 00F0 / 00F4 / 00F8 / 00FC / 0100 / 0104 / 0108 / 010C / 0110 / 0114 / 0118 / 011C / 0120 / 0124 / 0128 / 012C / 0130 / 0134 / 0138 / 013C / 0140 (level 31)

The Interrupt Vector Address register configures the Interrupt vector address for each interrupt level source.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### Register bit assignment

This is how the bits are assigned in each register, using data bits [07:00] as the example.

Bits	Access	Mnemonic	Reset	Description
D07	R/W	IE	0x0	<b>Interrupt enable</b> 0 Interrupt is disabled 1 Interrupt is enabled
D06	R	INV	0x0	<b>Invert</b> 0 Do not invert the level of the interrupt source. 1 Invert the level of the interrupt source.
D05	R/W	IT	0x0	<b>Interrupt type</b> 0 IRQ 1 FIQ If FIQ is programmed, <i>Interrupt</i> must be the highest priority.
D04:00	R/W	ISD	0x0– 0x1F	<b>Interrupt source ID</b> Assign an interrupt ID to each priority level. See “Interrupt sources,” beginning on page 149, for the list of interrupt ID numbers.

## ISADDR register

Address: A090 0164

The ISADDR register provides the current ISADDR value. Read and write to this register for IRQ interrupts only.

Immediately before the read to the ISADDR register, always perform an extra write or read to any other internal register to consume an extra clock cycle. Make sure that the extra access is not optimized away.

## Register

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:00	R/W	IS addr	0x0	<b>Interrupt service routine address</b> <ul style="list-style-type: none"> <li>A read to this register updates the priority logic block and masks the current and any lower priority interrupt requests.</li> <li>Write the value of the interrupt level (0–31) to clear the current priority level.</li> </ul>

## Interrupt Status Active

Address: A090 0168

The Interrupt Status Active register shows the current active interrupt request.

## Register

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:00	R	ISA	0x0	<b>Interrupt status active</b> <p>Provides the status of all active, enabled interrupt request levels, where bit 0 is for the interrupt assigned to level 0, bit 1 is for the interrupt assigned to level 1, and so on through bit 31 for the interrupt assigned to level 31.</p>

## Interrupt Status Raw

Address: A090 016C

The Interrupt Status Raw register shows all current interrupt requests.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Interrupt status raw (ISRAW)															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Interrupt status raw (ISRAW)															

### Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:00	R	ISRAW	0x0	<b>Interrupt status raw</b> Provides the status of all active, enabled, and disabled interrupt request levels, where bit 0 is for the interrupt assigned to level 0, bit 1 is for the interrupt assigned to level 1, and so on through bit 31 for the interrupt assigned to level 31.

## Software Watchdog Configuration

Address: A090 0174

The Software Watchdog Configuration register configures the software watchdog timer operation.

### Register

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:29	R/W	CSC	0x000	<b>Clock scale control</b> 000 Full speed (149.9136/74.9568) 001 Divide by 2 (74.9568/37.4784) 010 Divide by 4 (37.4784/18.7392) 011 Divide by 8 (18.7393/9.3693) 100 Divide by 16 (9.3693/4.6848) 101 - 111 Reserved Determines the frequency of the system clock rates. The full speed rate is 150MHz for the CPU clock and 75MHz for the AHB clock. If CCSEL = 0, then the CPU clock will be the same frequency as the AHB clock, 74.9568 maximum. This register can be written on the fly.
D28:26	R/W	Max CSC	0x000	<b>Max clock scale control</b> 000 Full speed (149.9136/74.9568) 001 Divide by 2 (74.9568/37.4784) 010 Divide by 4 (37.4784/18.7392) 011 Divide by 8 (18.7393/9.3693) 100 Divide by 16 (9.3693/4.6848) The Max CSC bits determine the maximum system CPU and AHB clock frequencies when returning from low speed operation or sleep mode. They allow software control of the ramp up in order to reduce surge current on the power supplies. For example, the code could ramp up the speed in stages; from /16, to /8, to /4, to /2, to FULL speed. This register is only valid if the hardware clock scale control bit is set in the Power Management register. If CCSEL = 0, then the CPU clock will be the same frequency as the AHB clock, 74.9568 maximum.

## PLL Configuration register

Address: A090 0188

The PLL Configuration register configures the PLL. A write to this register reconfigures and resets the PLL.

### PLL frequency formula

This is the formula for PLL frequency:

$$\text{PLL Vco} = (\text{RefClk} / \text{NR} + 1) * \text{NF} + 1$$

$$\text{ClkOut} = \text{PLL Vco} / \text{OD} + 1$$

Restrictions:

- (RefClk / NR+1) range: 275KHz-550MHz
- PLL Vco range: 110MHz-550MHz

## AHB Bus Activity Status

Address: A090 022C

The AHB Bus Activity Status register is a read-only register that determines the activity on the AHB bus.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Act stat															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Act stat															

### Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:00	R	Act stat	0x0	<b>Bus activity status</b> Provides the CPU with the status of activity on the system bus, excluding the CPU. This register can be used to help determine when to enter sleep mode or to reduce the system clock frequencies.  The counter is reset each time a master accesses the AHB bus. The counter will saturate at all 1s.

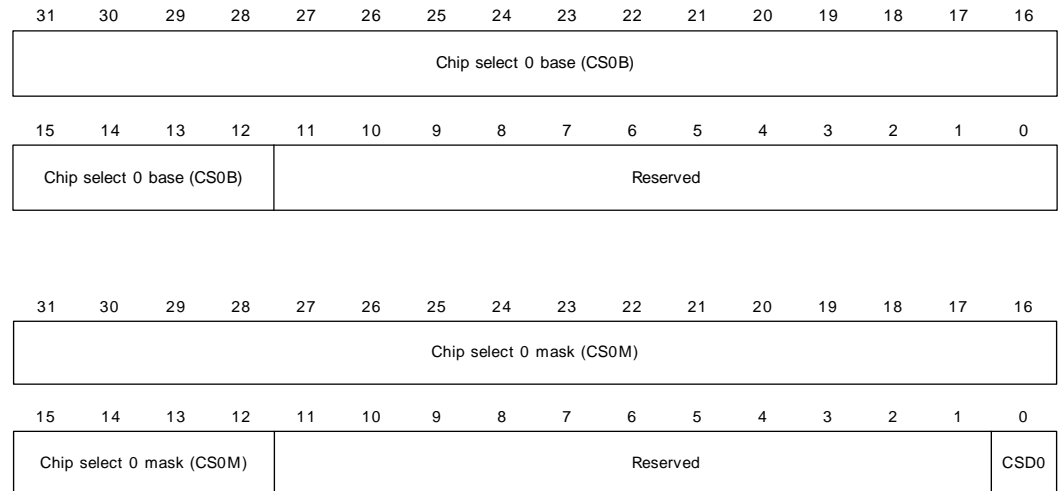

## System Memory Chip Select 0 Dynamic Memory Base and Mask registers

Addresses: A090 01D0 / 01D4

These control registers set the base and mask for system memory chip select 0, with a minimum size of 4K. The powerup default settings produce a memory range of 0x0000 0000 — 0x0FFF FFFF.

### Registers

### Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:12	R/W	CS0B	0x00000	<b>Chip select 0 base</b> Base address for chip select 0

D02	R	Int stat	0x0	<b>RTC module interrupt status</b> 0 RTC module interrupt not asserted 1 RTC module interrupt asserted Note: The RTC clock ready and RTC module interrupts are ORed together to the interrupt controller. Read this bit to determine the actual source.
D01	R/W	Standby mode	0x0	<b>RTC standby mode</b> Allows the RTC module to be placed in low power mode. 0 The RTC module is placed in standby mode and cannot be accessed by the CPU. The RTC clock must be enabled when in standby mode (bit 10). 1 Normal operation. The CPU must wait for the RTC interrupt and read the status to determine that the clock change is complete (RTC clock ready interrupt status bit is set). The clock change may take up to 30 microseconds after this bit is set. Note: This bit must be set to 0 when not accessing the RTC registers or battery back RAM. When early power loss interrupt is detected, set this bit to 0.
D00	R/W	Clk rdy int	0x0	<b>RTC clock ready interrupt clear</b> 0 RTC clock ready interrupt enabled 1 RTC clock ready interrupt cleared Note: This register must be set, then cleared to service the RTC clock ready interrupt.

# Memory Controller

## C H A P T E R 5

The Multiport Memory Controller is an AMBA-compliant system-on-chip (SoC) peripheral that connects to the Advanced High-performance Bus (AHB). The remainder of this chapter refers to this controller as the *memory controller*.

### Features

The memory controller provides these features:

- AMBA 32-bit AHB compliancy
- Dynamic memory interface support including SDRAM and JEDEC low-power SDRAM
- Asynchronous static memory device support including RAM, ROM, and Flash, with and without asynchronous page mode
- Can operate with cached processors with copyback caches
- Can operate with uncached processors
- Low transaction latency
- Read and write buffers to reduce latency and improve performance, particularly for uncached processors.
- 8-bit, 16-bit, and 32-bit wide static memory support.
- 16-bit and 32-bit wide chip select SDRAM memory support.
- Static memory features, such as:
  - Asynchronous page mode read
  - Programmable wait states
  - Bus turnaround delay
  - Output enable and write enable delays
  - Extended wait
- Power-saving modes that dynamically control SDRAM `clk_en`.
- Dynamic memory self-refresh mode supported by a power management unit (PMU) interface or by software.
- Controller supports 2K, 4K, and 8K row address synchronous memory parts; that is, typical 512 MB, 256 MB, and 16 Mb parts with 8, 16, or 32 DQ bits per device.

- A separate AHB interface to program the memory controller. This enables the memory controller registers to be situated in memory with other system peripheral registers.
- Locked AHB transaction support.
- Support for all AHB burst types.
- Little and big endian support.

**Note:** Synchronous static memory devices (synchronous burst mode) are not supported.

## Low-power operation

In many systems, the contents of the memory system have to be maintained during low-power sleep modes. The processor provides two features to enable this:

- Dynamic memory refresh over soft reset
- A mechanism to place the dynamic memories into self-refresh mode

Self-refresh mode can be entered as follows:

- 1 Set the SREFREQ bit in the Dynamic Memory Control register.
- 2 Poll the SREFACK bit in the Status register.

**Note:** Static memory can be accessed as normal when the SDRAM memory is in self-refresh mode.

### Low-power SDRAM deep-sleep mode

The memory controller supports JEDEC low-power SDRAM deep-sleep mode. Deep-sleep mode can be entered by setting the deep-sleep (DP) bit in the Dynamic Memory Control register. The device is put into a low-power mode where it is powered down and no longer refreshed. All data in the memory is lost.

### Low-power SDRAM partial array refresh

The memory controller supports JEDEC low-power SDRAM partial array refresh. Partial array refresh can be programmed by initializing the SDRAM memory device appropriately. When the memory device is put into self-refresh mode, only the memory banks specified are refreshed. The memory banks that are not refreshed lose their data contents.

## Memory map

The memory controller provides hardware support for booting from external nonvolatile memory. During booting, the nonvolatile memory must be located at address 0x00000000 in memory. When the system is booted, the SRAM or SDRAM

memory can be remapped to address 0x00000000 by modifying the address map in the AHB decoder.

Within System Control Module, see “Address decoding” on page 139 for the chip select memory addressing.

### Power-on reset memory map

On power-on reset, memory st\_cs1 is mirrored onto dy\_cs0 and st\_cs0. Any transactions to st\_cs0 or dy\_cs0 (or st\_cs1), then, access memory st\_cs1. Clearing the address mirror bit (M) in the Control register disables address mirroring, and memory st\_cs0, st\_cs1, and dy\_cs0 can be accessed as normal.

### Chip select 1 memory configuration

You can configure the memory width of st\_cs1 by using selected input signals. This allows you to boot from st\_cs1.

These are the bootstrap signals:

- gpio\_a[0], addr[23]: Memory width select
- gpio\_a[2]: Boot mode

### Example: Boot from flash, SRAM mapped after boot

The system is set up as:

- st\_cs1 is connected to the boot flash device.
- st\_cs0 is connected to the SRAM to be remapped to 0x00000000 after boot.

This is the boot sequence:

- 1 At power-on, the reset st\_cs1 is mirrored into st\_cs0 (and dy\_cs0).

- 2 When the power-on reset (`reset_n`) goes inactive, the processor starts booting from 0x00000000 in memory.
- 3 The software programs the optimum delay values in the flash memory so the boot code can run at full speed.
- 4 The code branches to `st_cs1` so the code can continue executing from the non-remapped memory location.
- 5 The appropriate values are programmed into the memory controller to configure `st_cs0`.
- 6 The address mirroring is disabled by clearing the address mirror (M) field in the Control register.
- 7 The ARM reset and interrupt vectors are copied from flash memory to SRAM that can then be accessed at address 0x00000000.
- 8 More boot, initialization, or application code is executed.

**Example: Boot from flash, SDRAM remapped after boot**

The system is set up as:

- `st_cs1` is connected to the boot flash device.
- `dy_cs0` is connected to the SDRAM to be remapped to 0x00000000 after boot.

This is the boot sequence:

- 1 At power-on, the reset `st_cs1` is mirrored into `dy_cs0` (and `st_cs0`).
- 2 When the power-on reset (`reset_n`) goes inactive, the processor starts booting from 0x00000000 in memory.
- 3 The software programs the optimum delay values in flash memory so the boot code can run at full speed.
- 4 The code branches to `st_cs1` so the code can continue executing from the non-remapped memory location.
- 5 The appropriate values are programmed into the memory controller to configure `dy_cs0`, and the memory device is initialized.
- 6 The address mirroring is disabled by clearing the address mirror (M) field in the Control register.
- 7 The ARM reset and interrupt vectors are copied from flash memory to SDRAM that can then be accessed at address 0x00000000.
- 8 More boot, initialization, or application code is executed.

**Boot from SPI to SDRAM**

SPI boot is selected if there is a pull-down on pin T14

`gpio_a[2]` / `addr[26]`: Boot mode

You can configure the SPI address width by pull-downs on pins R12 and T13

gpio\_a[0] / addr[24] and addr[23]: SPI configuration

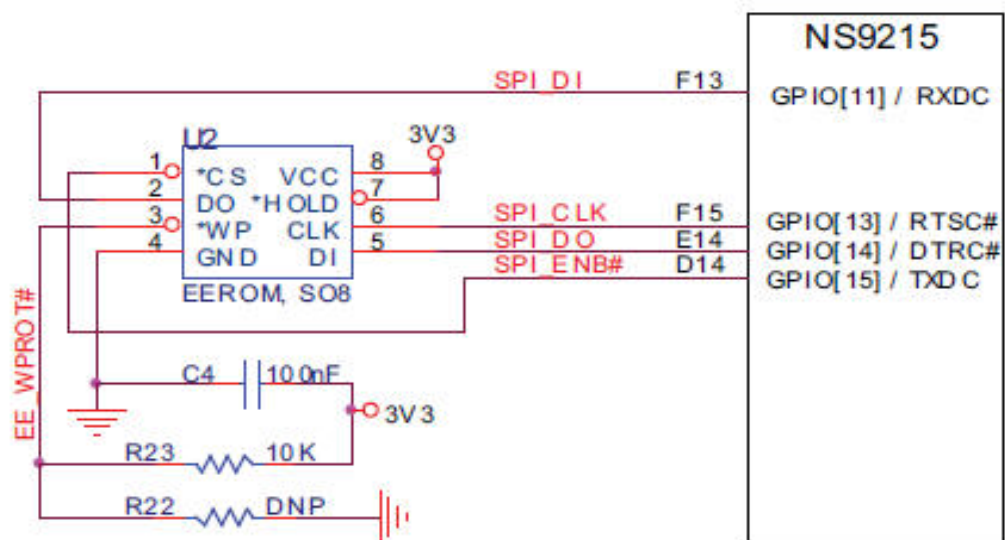

The NS9215 boots from an external, non-volatile, serial memory device. The device can be either a serial EEPROM or a serial Flash. In either case, the device must support a four-wire, mode0-compatible SPI interface.

The boot-over-SPI hardware interfaces to devices requiring an 8-bit address, 16-bit address, or 24-bit address.

The boot-over-SPI hardware requires several pieces of user-supplied information to complete the boot operation. This information must be located in a 128-byte header starting at address zero in the external memory device. Each entry in the header is four bytes long.

The figure below reflects the SPI memory connections.

For more information, see “Serial Control Module: SPI” on page 439.

## Static memory controller

This table shows configurations for the static memory controller with different types of memory devices. See “StaticMemory Configuration 0-3 registers” on page 252 for more information.

Device	Write protect	Page mode	Buffer
ROM	Enabled	Disabled	Disabled <sup>a</sup>
Page mode ROM	Enabled	Enabled	Enabled <sup>a</sup>

Device	Write protect	Page mode	Buffer
Extended wait ROM	Enabled	Disabled	Disabled <sup>a</sup>
SRAM	Disabled (or enabled) <sup>b</sup>	Disabled	Disabled <sup>a</sup>
Page mode SRAM	Disabled (or enabled) <sup>b</sup>	Enabled	Enabled <sup>a</sup>
Extended wait SRAM	Disabled (or enabled) <sup>b</sup>	Disabled	Disabled <sup>a</sup>
Flash	Disabled or (enabled) <sup>b</sup>	Disabled	Disabled <sup>c</sup>
Page mode flash	Disabled or (enabled) <sup>b</sup>	Enabled	Enabled <sup>c</sup>
Extended wait flash	Disabled or (enabled) <sup>b</sup>	Disabled	Disabled <sup>a</sup>
Memory mapped peripheral	Disabled (or enabled) <sup>b</sup>	Disabled	Disabled

<sup>a</sup> Enabling the buffers means that any access causes the buffer to be used. Depending on the application, this can provide performance improvements. Devices without async-page-mode support generally work better with the buffer disabled. Again, depending on the application, this can provide performance improvements.

<sup>b</sup> SRAM and Flash memory devices can be write-protected if required.

<sup>c</sup> Buffering must be disabled when performing Flash memory commands and during writes.

#### Notes:

- Buffering enables the transaction order to be rearranged to improve memory performance. If the transaction order is important, the buffers must be disabled.
- Extended wait and page mode cannot be enabled at the same time.

### Write protection

Each static memory chip select can be configured for write-protection. SRAM usually is unprotected and ROM devices must be write-protected (to avoid potential bus conflict when performing a write access to ROM), but the P field in the Static Memory Configuration register (see “StaticMemory Configuration 0-3 registers” on page 252) can be set to write-protect SRAM as well as ROM devices. If a write access is made to a write-protected memory bank, a bus error occurs. If a write access is made to a memory bank containing ROM devices and the chip select is not write-protected. An error is not returned and the write access proceeds as normal. Note that this might lead to a bus conflict.

### Extended wait transfers

The static memory controller supports extremely long transfer times. In normal use, the memory transfers are timed using the Static Memory Read Delay register (StaticWaitRd) and Static Memory Wait Delay register (StaticWaitWr). These registers allow transfers with up to 32 wait states. If a very slow static memory device has to be accessed, however, you can enable the static configuration extended wait (EW) bit. When EW is enabled, the Static Extended Wait register is used to time both the read and write transfers. The Static Extended Wait register allows transfers to have up to 16368 wait states.

A peripheral can, at any time, signal to the processor that it wants to complete an access early by asserting the `ns_ta_strb` signal. This allows a slow peripheral with variable access times to signal that it is ready to complete an access. The processor normally completes an access when it finds a rising edge on `ns_ta_strb`.

For a burst access, the peripheral must toggle `ns_ta_strb` for each access it wants to complete early. The peripheral is not required to assert `ns_ta_strb` for each access in the burst; for example, the peripheral requires the programmed access for the start of a four access burst followed by three early completion accesses, each signalled by the assertion of `ns_ta_strb`.

Using the `ns_ta_strb` signal is valid only when the EW bit is enabled.

**Be aware:**

- Using extremely long transfer times might mean that SDRAM devices are not refreshed correctly.
- Very slow transfers can degrade system performance, as the external memory interface is tied up for long periods of time. This has detrimental effects on time critical services, such as interrupt latency and low latency devices; for example, video controllers.

### Memory mapped peripherals

Some systems use external peripherals that can be accessed using the static memory interface. Because of the way many of these peripherals function, the read and write transfers to them must not be buffered. The buffer must therefore be disabled.

## Static memory initialization

Static memory must be initialized as required after power on reset (`reset_n`) by programming the relevant registers in the memory controller as well as the configuration registers in the external static memory device.

### Access sequencing and memory width

The data width of each external memory bank must be configured by programming the appropriate bank configuration register (Static Memory Configuration 0-3). When the external memory bus is narrower than the transfer initiated from the current main bus master, the internal bus transfer takes several external bus transfers to complete.

For example, if bank 0 is configured as 8-bit wide memory and a 32-bit read is initiated, the AHB bus stalls while the memory controller reads four consecutive bytes from the memory. During these accesses, the static memory controller block demultiplexes the four bytes into one 32-bit word on the AHB bus.

**Wait state generation**

Each bank of the memory controller must be configured for external transfer wait states in read and write accesses.

Configure the banks by programming the appropriate bank control registers:

- “StaticMemory Configuration 0-3 registers” on page 252 (StaticConfig[n])
- “StaticMemory Write Enable Delay 0-3 registers” on page 254 (StaticWaitWen[n])
- “Static Memory Output Enable Delay 0-3 registers” on page 255 (StaticWaitOen[n])
- “Static Memory Read Delay 0-3 registers” on page 256 (StaticWaitRd[n])
- “Static Memory Write Delay 0-3 registers” on page 258 (StaticWaitWr[n])
- “StaticMemory Page Mode Read Delay 0-3 registers” on page 257 (StaticWaitPage[n])
- “StaticMemory Turn Round Delay 0-3 registers” on page 259 (StaticWaitTurn[n])
- “Static Memory Extended Wait register” on page 247 (StaticExtendedWait)

The number of cycles in which an AMBA transfer completes is controlled by two additional factors:

- Access width
- External memory width

**Programmable enable**

Each bank of the memory controller has a programmable enable for the extended wait (EW). The WAITRD wait state field in the Static Memory Read Delay register can be programmed to select from 1-32 wait states for read memory accesses to SRAM and ROM, or the initial read access to page mode devices. The WAITWR wait state field in the Static Memory Write Delay register can be programmed to select from 1-32 wait states for access to SRAM. The Static Memory Page Mode Read Delay register can be programmed to select from 1-32 wait states for page mode accesses.

**Static memory read control**

There are three types of static memory read controls:

- Output enable programmable delay
- ROM, SRAM, and flash
- Asynchronous page mode read

**Output enable programmable delay**

The delay between the assertion of the chip select and the output enable is programmable from 0 to 15 cycles using the wait output enable bits (WAITOEN) in the Static Memory Output Enable Delay registers. The delay is used to reduce power

consumption for memories that cannot provide valid output data immediately after the chip select has been asserted. The output enable is always deasserted at the same time as the chip select, at the end of the transfer.

## ROM, SRAM, and Flash

The memory controller uses the same read timing control for ROM, SRAM, and flash devices. Each read starts with the assertion of the appropriate memory bank chip select signals ( $cs_n$ ) and memory address ( $addr[27:0]$ ). The read access time is determined by the number of wait states programmed for the WAITRD field in the Static Memory Read Delay register. The WAITTURN field in the Static Memory Turn Round Delay register determines the number of bus turnaround wait states added between external read and write transfers.

## Static memory read: Timing and parameters

This section shows static memory read timing diagrams and parameters.

### External memory read transfer with zero wait states

This diagram shows an external memory read transfer with the minimum zero wait states ( $WAITRD=0$ ). Maximum performance is achieved when accessing the external device with load multiple (LDM) or store multiple (STM) CPU instructions.

Timing parameter	Value
WAITRD	0
WAITOEN	0
WAITPAGE	N/A
WAITWR	N/A
WAITWEN	N/A
WAITTURN	N/A

### External memory read transfer with two wait states

This diagram shows an external memory read transfer with two wait states ( $WAITRD=2$ ). Seven AHB cycles are required for the transfer, five for the standard read access and an additional two because of the programmed wait states added ( $WAITRD$ ).

## MEMORY CONTROLLER

### Static memory read: Timing and parameters

Timing parameter	Value
WAITRD	2
WAITOEN	0
WAITPAGE	N/A
WAITWR	N/A
WAITEN	N/A
WAITTURN	N/A

### External memory read transfer with two output enable delay states

This diagram shows an external memory read transfer with two output enable delay states (WAITOEN=2). Seven AHB cycles are required for the transfer, five for the standard read and an additional two because of the output delay states added.

Timing parameter	Value
WAITRD	2
WAITOEN	2
WAITPAGE	N/A
WAITWR	N/A
WAITWEN	N/A
WAITTURN	N/A

### External memory read transfers with zero wait states

This diagram shows external memory read transfers with zero wait states (WAITRD=0). These transfers can be non-sequential transfers or sequential transfers of a specified burst length. Bursts of unspecified length are interpreted as INCR4 transfers. All transfers are treated as separate reads, so have the minimum of five AHB cycles added.

Timing parameter	Value
WAITRD	0
WAITOEN	0
WAITPAGE	N/A
WAITWR	N/A
WAITWEN	N/A
WAITTURN	N/A

### Burst of zero wait states with fixed length

This diagram shows a burst of zero wait state reads with the length specified. Because the length of the burst is known, the chip select can be held asserted during the whole burst and generate the external transfers before the current AHB transfer has completed. The first read requires five arbitration cycles; the three subsequent sequential reads have zero AHB cycles added because the external transfers are automatically generated.

Timing parameter	Value
WAITRD	0
WAITOEN	0
WAITPAGE	N/A
WAITWR	N/A

Timing parameter	Value
WAITWEN	N/A
WAITTURN	N/A

**Burst of two wait states with fixed length**

This diagram shows a burst of two wait state reads with the length specified. The WAITRD value is used for all transfers in the burst.

Timing parameter	Value
WAITRD	2
WAITOEN	0
WAITPAGE	N/A
WAITWR	N/A
WAITWEN	N/A
WAITTURN	N/A

**Asynchronous page mode read**

The memory controller supports asynchronous page mode read of up to four memory transfers by updating address bits addr[1] and addr[0]. This feature increases the bandwidth by using a reduced access time for the read accesses that are in page mode. The first read access takes static wait read and WAITRD cycles. Subsequent read accesses that are in page mode take static wait page and WAITPAGE cycles. The chip select and output enable lines are held during the burst, and only the lower two address bits change between subsequent accesses. At the end of the burst, the chip select and output enable lines are deasserted together.

**Asynchronous page mode read: Timing and parameters**

This section shows asynchronous page mode read timing diagrams and parameters.

### External memory page mode read transfer

This diagram shows an external memory page mode read transfer with two initial wait states and one sequential wait state. The first read requires five AHB arbitration cycles (plus three wait states); the following (up to 3) sequential transfers have only one AHB wait state. This gives increased performance over the equivalent nonpage mode ROM timing.

Timing parameter	Value
WAITRD	2
WAITOEN	0
WAITPAGE	1
WAITWR	N/A
WAITWEN	N/A
WAITTURN	N/A

### External memory 32-bit burst read from 8-bit memory

This diagram shows a 32-bit read from an 8-bit page mode ROM device, causing four burst reads to be performed. A total of eight AHB wait states are added during this transfer, five AHB arbitration cycles and then one for each of the subsequent reads. WAITRD and WAITPAGE are 0.

Timing parameters	Value
WAITRD	0
WAITOEN	0
WAITPAGE	0
WAITWR	N/A
WAITWEN	N/A
WAITTURN	N/A

## Static memory write control

### Write enable programming delay

The delay between the assertion of the chip select and the write enable is programmable from 1 to 16 cycles using the WAITWEN bits of the Static Memory Write Enable Delay (StaticWaitWen[3:0]) registers. The delay reduces the power consumption for memories. The write enable is asserted on the rising edge of HCLK after the assertion of the chip select for zero wait states. The write enable is always deasserted a cycle before the chip select, at the end of the transfer. datamask\_n (byte lane signal) has the same timing as st\_we\_n (write enable signal) for writes to 8-bit devices that use the byte lane selects instead of the write enables.

### SRAM

Write timing for SRAM starts with assertion of the appropriate memory bank chip selects ( $cs[n]_n$ ) and address signals ( $addr[27:0]_n$ ). The write access time is determined by the number of wait states programmed for the WAITWR field in the Static Memory Write Delay register (see “Static Memory Write Delay 0-3 registers” on page 258). The WAITTURN field in the bank control register (see “StaticMemory Turn Round Delay 0-3 registers” on page 259) determines the number of bus turnaround wait states added between external read and write transfers.

## Static memory Write: Timing and parameters

This section shows static memory write timing diagrams and parameters.

### External memory write transfer with zero wait states

This diagram shows a single external memory write transfer with minimum zero wait states (WAITWR=0). One wait state is added.

Timing parameters	Value
WAITRD	N/A
WAITOEN	N/A
WAITPAGE	N/A
WAITWR	0
WAITWEN	0
WAITTURN	N/A

### External memory write transfer with two wait states

This diagram shows a single external memory write transfer with two wait states (WAITWR=2). One AHB wait state is added.

Timing parameter	Value
WAITRD	N/A
WAITOEN	N/A
WAITPAGE	N/A
WAITWR	2
WAITWEN	0
WAITTURN	N/A

### External memory write transfer with two write enable delay states

This diagram shows a single external memory write transfer with two write enable delay states (WAITWEN=2). One wait state is added.

## MEMORY CONTROLLER

### Static memory Write: Timing and parameters

Timing parameters	Value
WAITRD	N/A
WAITOEN	N/A
WAITPAGE	N/A
WAITWR	2
WAITWEN	2
WAITTURN	N/A

#### Two external memory write transfers with zero wait states

This diagram shows two external memory write transfers with zero wait states ( $\text{WAITWR}=0$ ). Four AHB wait states are added to the second write, because this write can be started only when the first write has completed. This is the timing of any sequence of write transfers, nonsequential to nonsequential or nonsequential to sequential, with any value of  $\text{HBURST}$ . The maximum speed of write transfers is controlled by the external timing of the write enable relative to the chip select, so all external writes must take two cycles to complete: the cycle in which write enable is asserted and the cycle in which write enable is deasserted.

Timing parameter	Value
WAITRD	N/A
WAITOEN	N/A
WAITPAGE	N/A
WAITWR	0
WAITWEN	0
WAITTURN	0

#### Flash memory

Write timing for flash memory is the same as for SRAM devices.

## Bus turnaround

The memory controller can be configured for each memory bank to use external bus turnaround cycles between read and write memory accesses. The WAITTURN field can be programmed for 1 to 16 turnaround wait states, to avoid bus contention on the external memory databus. Bus turnaround cycles are generated between external bus transfers as follows:

- Read to read (different memory banks)
- Read to write (same memory bank)
- Read to write (different memory banks)

## Bus turnaround: Timing and parameters

This section shows bus turnaround timing diagrams and parameters.

### Read followed by write with no turnaround

This diagram shows a zero wait read followed by a zero wait write with default turnaround between the transfers of two cycles because of the timing of the AHB transfers. Standard AHB wait states are added to the transfers, five for the read and three for the write.

Timing parameter	Value
WAITRD	0
WAITOEN	0
WAITPAGE	N/A
WAITWR	0
WAITWEN	0
WAITTURN	0

Write followed by  
a read with no  
turnaround

This diagram shows a zero wait write followed by a zero wait read with default turnaround between the transfers of one cycle. Three wait states are added to the write transfer; five wait states are added to the read transfer. The five AHB arbitration cycles for the read transfer include two wait states to allow the previous write access to complete and the three standard wait states for the read transfer.

Timing parameter	Value
WAITRD	0
WAITOEN	0
WAITPAGE	N/A
WAITWR	0
WAITWEN	0
WAITTURN	0

Read followed by  
a write with two  
turnaround cycles

Its diagram shows a zero wait read followed by a zero wait write with two turnaround cycles added. The standard minimum of three AHB arbitration cycles is added to the read transfer and two wait states are added to the write transfer (as for any read-write transfer sequence).

Timing parameters	Value
WAITRD	0
WAITOEN	0
WAITPAGE	N/A
WAITWR	0
WAITWEN	0
WAITTURN	2

## Address connectivity

### Address/Data Bus Connectivity

Address/Data Bus LSB: Regardless of Endianness

A0 is always the least significant bit for 8-bit peripherals,

A1 is always the least significant bit for 16-bit peripherals,

A2 is always the least significant bit for 32-bit peripherals,

D24 is always the least significant bit for 8-bit peripherals,

D16 is always the least significant bit for 16-bit peripherals,

D00 is always the least significant bit for 32-bit peripherals,

8 bit peripherals are aligned with D31-24.

The four external memory cycles require both A1 and A0.

16 bit peripherals are aligned with D31-16.

The two external memory cycles require the state of A1 and not A0

32 bit peripherals are aligned with D31-0.

The single external memory cycle does not require the state of A1 or A0

**Note:** In comparison to the NS97xx/9360 - which has the Address/Data lines Right Justified.

- No matter what the data bus width, A0 always connects to peripheral A0,
- D[7-0] always connects to peripheral D[7-0].

### Byte lane control

The memory controller generates the byte lane control signals `data_mask[3:0]` according to these attributes:

- Little or big endian operation
- Transfer width
- External memory bank databus width, defined within each control register
- The decoded address value for write accesses only

Word transfers are the largest size transfers supported by the memory controller. Any access tried with a size greater than a word causes an error response. Each memory chip select can be 8, 16, or 32 bits wide. The memory type used determines how the `st_we_n` and `data_mask` signals are connected to provide byte, halfword, and word access.

For read accesses, you must control the `data_mask` signals by driving them all high or all low. Do this by programming the byte lane state (PB) bit in the Static Configuration [3:0] register.

PB = 0: sram `we_n` strobes - can be used as `we_n` for selective byte writes for x8 srams that make up a x16, or x32 memory bank

PB = 1: sram byte lane enables - can be used to control the Upper and Lower byte selection for srams that have byte lane inputs. With this setting `we_n` can be used to control the sram `WE_n` input, instead of the respective `data_mask` signal.

See "Address connectivity" on page 219 for additional information, with respect to `st_we_n` and `data_mask`, for different memory configurations.

## Byte lane configuration in regard to Endianness

### Byte lane configuration for 32-bit peripherals

Data_mask	Active data bus lane	Little Endian byte address	Big Endian byte address	Little Endian word address	Big Endian word address
data_mask[3]	D31:24	3	0	1	0
data_mask[2]	D23:16	2	1		
data_mask[1]	D15:08	1	2	0	1
data_mask[0]	D07:00	0	3		

### Byte lane configuration for 16-bit peripherals

Data_mask	Active data bus lane	Little Endian byte address	Big Endian byte address
data_mask[3]	D31:24	1	0
data_mask[2]	D23:16	0	1

### Byte lane configuration for 8-bit peripherals

Data_mask	Active data bus lane
data_mask[3]	D31:24

**Note:** The NS97xx/9360 byte lane configuration can be found in the respective Hardware Reference Manuals in the Memory Controller chapter under Byte lane control and databus steering

### Memory banks constructed from 8-bit or non-byte-partitioned memory devices

For memory banks constructed from 8-bit or non-byte-partitioned memory devices, it is important that the byte lane state (PB) bit is cleared to 0 within the respective memory bank control register. This forces all data\_mask lines high during a read access, as the byte lane selects are connected to the device write enables.

The next figure shows 8-bit memory configuring memory banks that are 8-, 16-, and 32-bits wide. In each of these configurations, the data\_mask[3:0] signals are connected

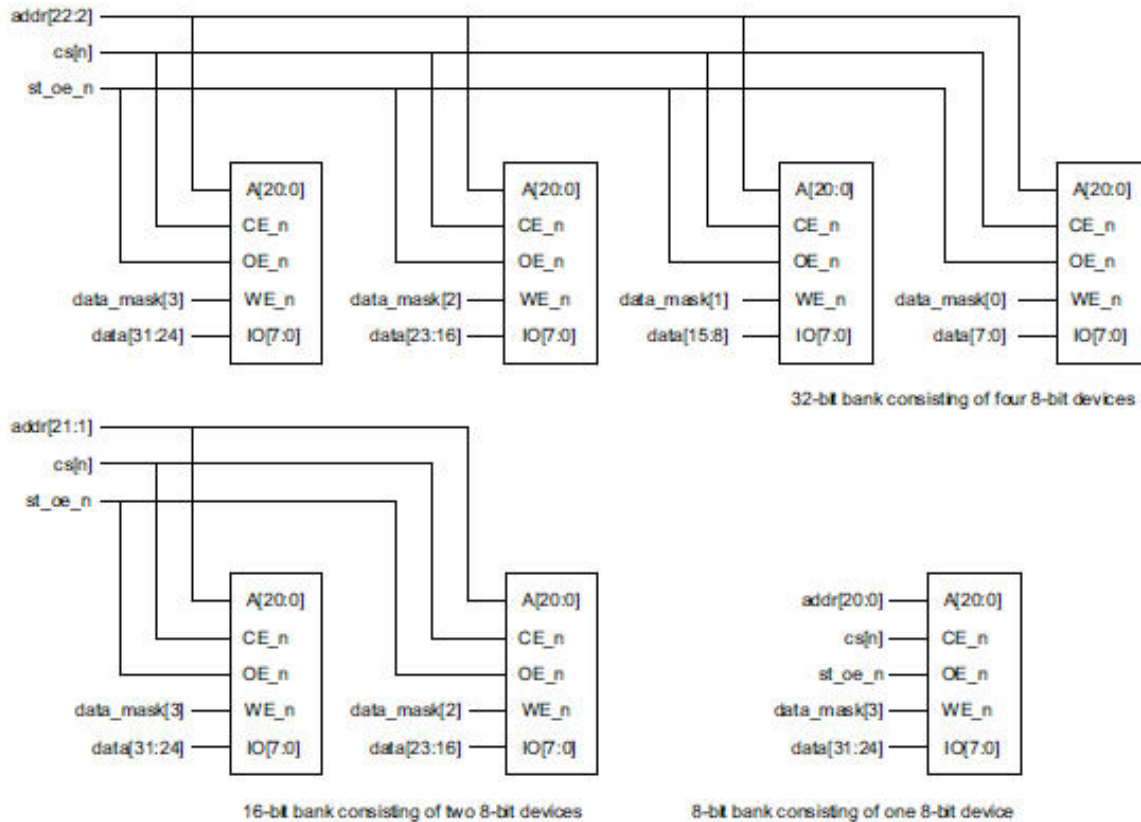

## MEMORY CONTROLLER

### Byte lane configuration in regard to Endianness

to write enable (WE<sub>n</sub>) inputs of each 8-bit memory. The st\_we\_n signal from the memory controller is not used.

- For write transfers, the appropriate data\_mask[3:0] byte lane signals are asserted low, and direct the data to the addressed bytes.
- For read transfers, all data\_mask[3:0] signals are deasserted high, enabling the external bus to be defined for at least the width of the accessed memory.

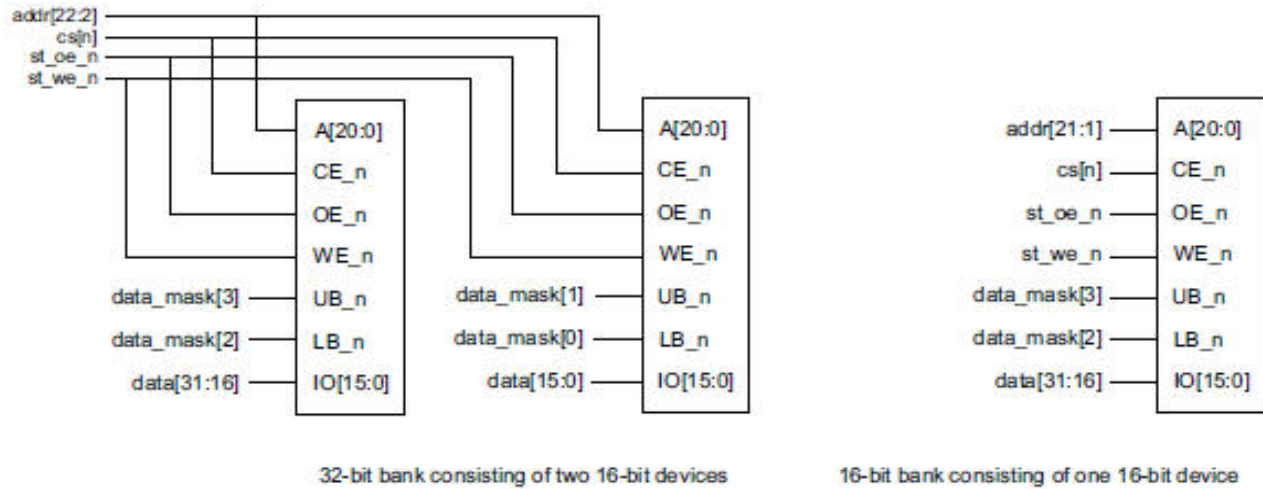

### Memory banks constructed from 16-or 32-bit memory devices

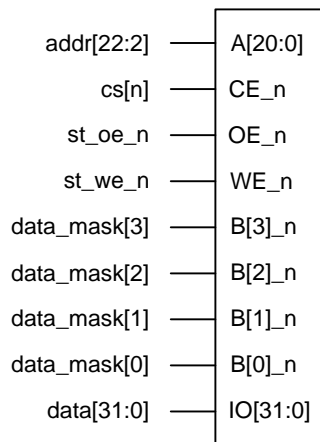

For memory banks constructed from 16- or 32-bit memory devices, it is important that the byte lane select (PB) bit is set to 1 within the respective memory bank control register. This asserts all data\_mask[3:0] lines low during a read access as, during a read, all device bytes must be selected to avoid undriven byte lanes on the read data value. With 16- and 32-bit wide memory devices, byte select signals exist and must be appropriately controlled; see the next two figures.

### Memory banks constructed from 16-bit memory

### Memory bank constructed from 32-bit memory

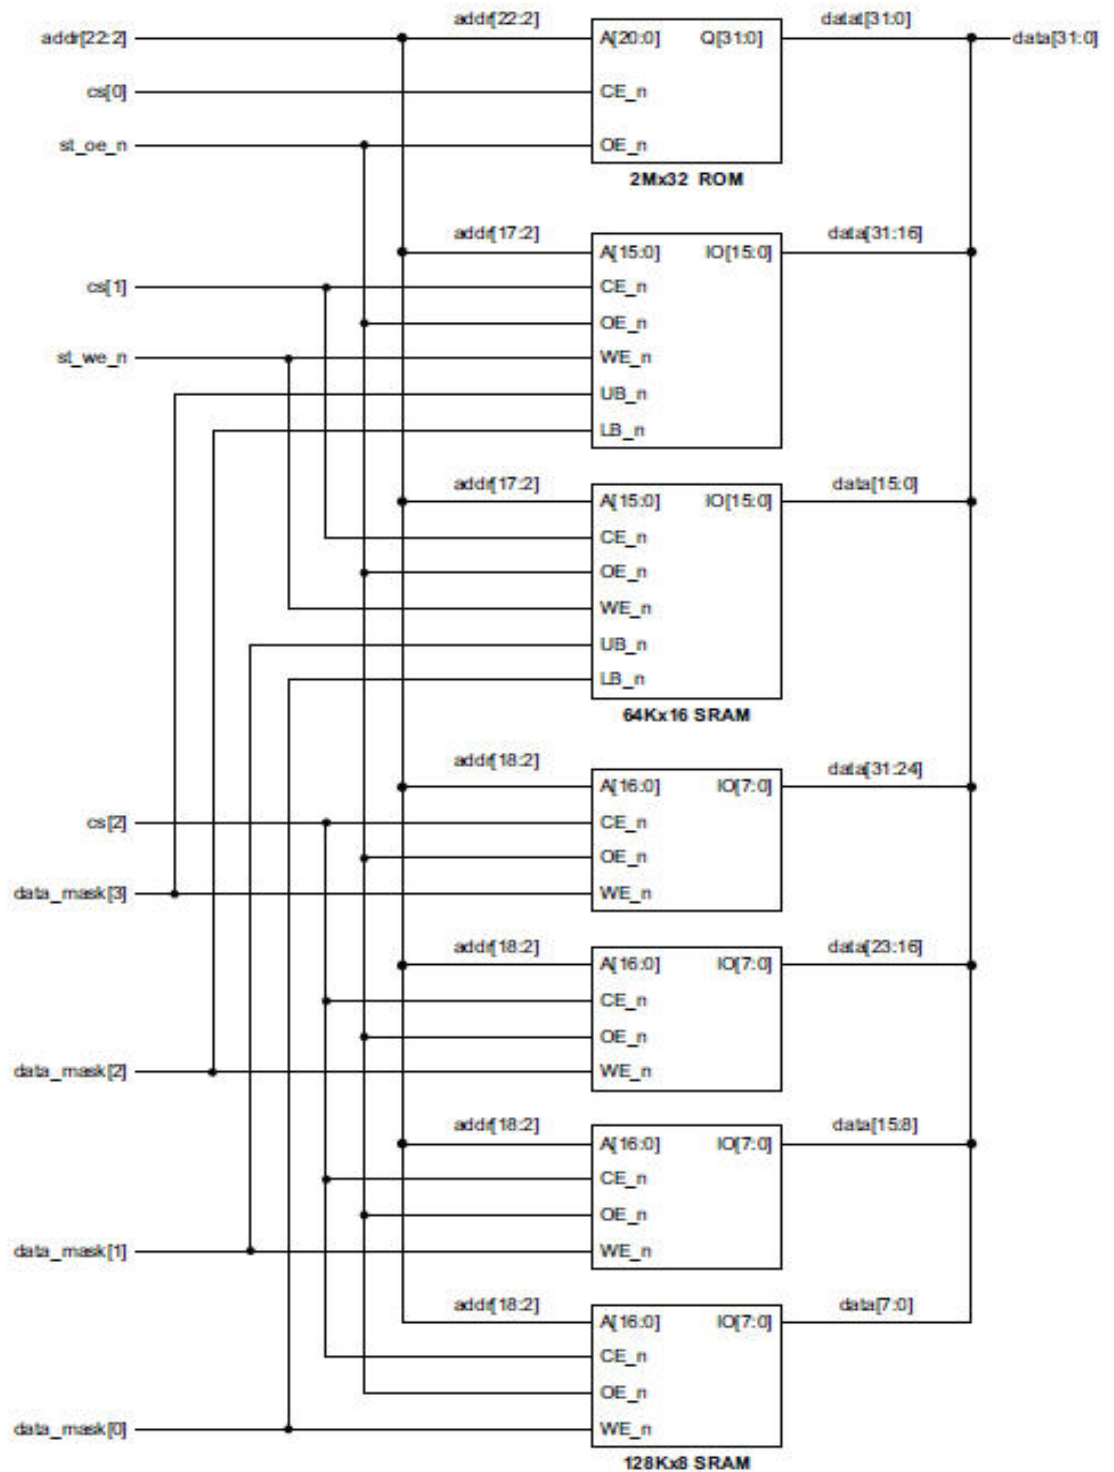

32-bit bank consisting of one 32-bit device

The next figure shows connections for a typical memory system with different data width memory devices.

## MEMORY CONTROLLER

Byte lane configuration in regard to Endianness

## Dynamic memory controller

### Write protection

Each dynamic memory chip select can be configured for write-protection by setting the appropriate bit in the write protect (P) field on the Dynamic Memory Configuration register. If a write access is performed to a write-protected memory bank, a bus error is generated.

### Access sequencing and memory width

The data width of each chip select must be configured by programming the appropriate Dynamic Memory Configuration register. When the chip select data bus width is narrower than the transfer initiated from the current bus master, the internal bus transfer takes several external bus transfers to complete. If chip select 4 is configured as 16-bit wide memory, for example, and a 32-bit read is initiated, the AHB bus stalls while the memory controller reads two consecutive words from memory. During these accesses, the memory controller block demultiplexes the two 16-bit words into one 32-bit word and places the result onto the AHB bus.

Word transfers are the widest transfers supported by the memory controller. Any access tried with a size larger than a word generates an error response.

## SDRAM Initialization

These steps show how to initialize an external SDRAM device:

- 1 Wait 100 ms after powerup and clocks have stabilized.
- 2 Set the SDRAM<sub>Init</sub> value in the Dynamic Control register to 11 — Issue SDRAM NOP command.
- 3 Wait 200 ms.
- 4 Set the SDRAM<sub>Init</sub> value in the Dynamic Control register to 10 — Issue SDRAM PALL (precharge all) command. This precharges all banks and places the SDRAM device into the *all banks idle* state.
- 5 Force frequent refresh cycles by writing a 1 to the Dynamic Refresh register. This provides a memory refresh every 16 memory clock cycles.
- 6 Wait until eight SDRAM refresh cycles have occurred (128 memory clock cycles).
- 7 Program the appropriate operational value to the Dynamic Refresh register.
- 8 Program the appropriate operational value to the Dynamic Ras and Cas *N*/register.
- 9 Program the appropriate operational value to the Dynamic Configuration *N*/register, with the exception of the buffer enable bit, which must be set to 0 during initialization.

- 10 Set the SDRAM<sub>Init</sub> value in the Dynamic Control register to 01 — Issue SDRAM Mode command.
- 11 Program the SDRAM memory 10-bit mode register. The mode register enables these parameters to be programmed:

Bit	Parameter	Parameter description
02:00	Burst length	<ul style="list-style-type: none"> <li>■ 4 for a 32-bit wide external bus</li> <li>■ 8 for a 16-bit wide external bus</li> </ul>
03	Burst type	Sequential
06:04	CAS latency	Dependent on the SDRAM device and operating frequency
08:07	Operating mode	Standard operation
09	Write burst mode	Programmed burst length

A read transaction from the SDRAM memory programs the mode register. The transfer address contains the value to be programmed. Address bits 31:28 determine the chip select of the specific SDRAM that is being programmed. The 10-bit mode value must be shifted left per the specific device being programmed; see the tables following this procedure to determine the left shift value.

All other address bits must be set to 0.

- 12 Set the SDRAM<sub>Init</sub> value in the Dynamic Control register to 00 — Issue SDRAM normal operation command.
- 13 Enable the buffers by writing a 1 to the buffer enable bit in the Dynamic Configuration *N* register.

The SDRAM is now ready for normal operation.

**Left-shift value table: 32-bit wide data bus SDRAM (RBC)**

A070 0268	StaticWaitOen3	Static Memory Output Enable Delay 3
A070 026C	StaticWaitRd3	Static memory Read Delay 3
A070 0270	StaticWaitPage3	Static Memory Page Mode Read Delay 3
A070 0274	StaticWaitWr3	Static Memory Write Delay 3
A070 0278	StaticWaitTurn3	Static Memory Turn Round Delay 3

### Reset values

Reset values will be noted in the description column of each register table, rather than as a separate column.

## Control register

Address: A070 0000

The Control register controls the memory controller operation. The control bits can be changed during normal operation.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													LPM	ADDM	MCEN

## Register bit assignment

Bits	Access	Mnemonic	Description
D31:03	N/A	Reserved	N/A (do not modify)
D02	R/W	LPM	<p><b>Low-power mode</b></p> <p>0 Normal mode (reset value on reset_n)</p> <p>1 Low-power mode</p> <p>Indicates normal or low-power mode. Entering low-power mode reduces memory controller power consumption. Dynamic memory is refreshed as necessary. The memory controller returns to normal functional mode by clearing the low-power mode bit or by power-on reset.</p> <p>If you modify this bit, be sure the memory controller is in idle state.</p> <p>If you modify the L bit, be aware of these conditions:</p> <ul style="list-style-type: none"> <li>■ The external memory cannot be accessed in low-power or disabled state. If a memory access is performed in either of these states, an error response is generated.</li> <li>■ The memory controller AHB programming port can be accessed normally.</li> <li>■ The memory controller registers can be programmed in low-power and/or disabled state.</li> </ul>
D01	R/W	ADDM	<p><b>Address mirror</b></p> <p>0 Normal memory map</p> <p>1 Reset memory map. Static memory chip select 1 is mirrored onto chip select 0 and chip select 4 (reset value on reset_n)</p> <p>Indicates normal or reset memory map. On power-on reset, chip select 1 is mirrored to both chip select 0 and chip select 1/chip select 4 memory areas. Clearing the M bit allows chip select 0 and chip select 4 memory to be accessed.</p>
D00	R/W	MCEN	<p><b>Memory controller enable</b></p> <p>0 Disabled</p> <p>1 Enabled (reset value on reset_n)</p> <p>Disabling the memory controller reduces power consumption. When the memory controller is disabled, the memory is not refreshed. The memory controller is enabled by setting the enable bit or by power-on reset.</p> <p>If you modify this bit, be sure the memory controller is in idle state.</p> <p>If you modify the E bit, be aware of these conditions:</p> <ul style="list-style-type: none"> <li>■ The external memory cannot be accessed in low-power or disabled state. If a memory access is performed in either of these states, an error response is generated.</li> <li>■ The memory controller AHB programming port can be accessed normally.</li> <li>■ The memory controller registers can be programmed in low-power and/or disabled state.</li> </ul>

## Status register

Address: A070 0004

The Status register provides memory controller status information.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													SA	WBS	BUSY

### Register bit assignment

Bits	Access	Mnemonic	Description
D31:03	N/A	Reserved	N/A (do not modify)
D02	R	SA	<b>Self-refresh acknowledge (SREFACK)</b> 0 Normal mode 1 Self refresh mode (reset value on reset_n) Indicates the memory controller operating mode.
D01	R	WBS	<b>Write buffer status</b> 0 Write buffers empty (reset value on reset_n) 1 Write buffers contain data Enables the memory controller to enter low-power mode or disabled mode cleanly.
D00	R	BUSY	<b>Busy</b> 0 Memory controller is idle 1 Memory controller is busy performing memory transactions, commands, or auto-refresh cycles, or is in self-refresh mode (reset value on reset_n). Ensures that the memory controller enters the low-power or disabled state cleanly by determining whether the memory controller is busy.

## Configuration register

Address: A070 0008

The Configuration register configures memory controller operation. It is recommended that this register be modified during system initialization, or when there are no current or outstanding transactions. Wait until the memory controller is idle, then enter low-power or disabled mode.

## Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															END

## Register bit assignment

Bits	Access	Mnemonic	Description
D31:01	N/A	Reserved	N/A (do not modify)
D00	R/W	END	<p>Endian mode</p> <p>0 Little endian mode</p> <p>1 Big endian mode</p> <p>The value of the endian bit on power-on reset (reset_n) is determined by the gpio_a[3] signal. This value can be overridden by software.</p> <p>Note: The value of the gpio_a[3] signal is reflected in this field. When programmed, this register reflects the last value written into the register. You must flush all data in the memory controller before switching between little endian and big endian modes.</p>

## Dynamic Memory Control register

Address: A070 0020

The Dynamic Memory Control register controls dynamic memory operation. The control bits can be changed during normal operation.

## Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Rsvd	nRP	Not used	Reserved				SDRAMInit	Rsvd	Not used	Reserved		SR	Not used	CE	

## Register bit assignment

Bits	Access	Mnemonic	Description
D31:15	N/A	Reserved	N/A (do not modify)
D14	R/W	nRP	<b>Sync/Flash reset/power down signal (dy_pwr_n)</b> 0 dy_pwr_n signal low (reset value on reset_n) 1 Set dy_pwr_n signal high
D13	R/W	Not used	Always write to 0.
D12:09	N/A	Reserved	N/A (do not modify)
D08:07	R/W	SDRAMInit	<b>SDRAM initialization</b> 00 Issue SDRAM NORMAL operation command (reset value on reset_n) 01 Issue SDRAM MODE command 10 Issue SDRAM PALL (precharge all) command 11 Issue SDRAM NOP (no operation) command
D06	N/A	Reserved	N/A (do not modify)
D05	R/W	Not used	Must write 0.
D04:03	N/A	Reserved	N/A (do not modify)
D02	R/W	SR	<b>Self-refresh request (SREFREQ)</b> 0 Normal mode 1 Enter self-refresh mode (reset value on reset_n) By writing 1 to this bit, self-refresh can be entered under software control. Writing 0 to this bit returns the memory controller to normal mode. The self-refresh acknowledge bit in the Status register must be polled to discover the current operating mode of the memory controller. Note: The memory controller exits from power-on reset with the self-refresh bit on high. To enter normal functional mode, set the self-refresh bit low. Writing to this register with the bit set to high places the register into self-refresh mode. This functionality allows data to be stored over SDRAM self-refresh of the ASIC is powered down.
D01	R/W	Not used	Must write 1.
D00	R/W	CE	<b>Dynamic memory clock enable</b> 0 Clock enable if idle devices are deasserted to save power (reset value on reset_n) 1 All clock enables are driven high continuously. Note: Clock enable must be high during SDRAM initialization.

## Dynamic Memory Refresh Timer register

Address: A070 0024

The Dynamic Memory Refresh Timer register configures dynamic memory operation. It is recommended that this register be modified during system initialization, or when there are no current or outstanding transactions. Wait until the memory controller is idle, then enter low-power or disabled mode. These bits can, however, be changed during normal operation if necessary.

**Note:** The Dynamic Memory Refresh Timer register is used for all four dynamic memory chip selects. The worst case value for all chip selects must be programmed.

## Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						REFRESH									

## Register bit assignment

Bits	Access	Mnemonic	Description
D31:11	N/A	Reserved	N/A (do not modify)
D10:00	R/W	REFRESH	<b>Refresh timer</b> 0x0 Refresh disabled (reset value on reset_n) 0x1–0x77F n(x16) 16n clk_out ticks between SDRAM refresh cycles

**Note:** The refresh cycles are evenly distributed. There might be slight variations, however, when the auto-refresh command is issued, depending on the status of the memory controller.

## Refresh period calculations

$$\text{REFRESH} = ((64\text{e-}3 / \text{\#rows}) * \text{CLKOUTe} + 6) / 16$$

The result is Dec; convert to Hex for entry into register.

For 4k Rows:

$$\text{REFRESH} = 15.625\mu\text{s} \text{ (4096 refresh cycles every 64 ms)}$$

For 8K Rows

$$\text{REFRESH} = 7.812\mu\text{s} \text{ (8192 refresh cycles every 64 ms)}$$

## Dynamic Memory Read Configuration register

Address: A070 0028

The Dynamic Memory Read Configuration register allows you to configure the dynamic memory read strategy. Modify this register only during system initialization.

**Note:** The Dynamic Memory Read Configuration register is used for all four dynamic memory chip selects. The worst case value for all chip selects must be programmed.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														RD	

### Register bit assignment

Bits	Access	Mnemonic	Description
D31:02	N/A	Reserved	N/A (do not modify)
D01:00	R/W	RD	<b>Read data strategy</b> 00 Reserved. 01 Command delayed strategy, using CLKDELAY (command delayed, clock out not delayed). 10 Command delayed strategy plus one clock cycle, using CLKDELAY (command delayed, clock out not delayed). 11 Command delayed strategy plus two clock cycles, using CLKDELAY (command delayed, clock out not delayed).

## Dynamic Memory Precharge Command Period register

Address: A070 0030

The Dynamic Memory Precharge Command Period register allows you to program the precharge command period,  $t_{RP}$ . Modify this register only during system initialization. This value normally is found in SDRAM datasheets as  $t_{RP}$ .

**Note:** The Dynamic Memory Precharge Command Period register is used for all four dynamic memory chip selects. The worst case value for all chip selects must be programmed.

## Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## Register bit assignment

Bits	Access	Mnemonic	Description
D31:04	N/A	Reserved	N/A (do not modify)
D03:00	R/W	RP	<b>Precharge command period (<math>t_{RP}</math>)</b> 0x0–0xE n+1 clock cycles, where the delay is in clk_out cycles. <b>0xF</b> 16 clock cycles (reset value on reset_n)

## Dynamic Memory Active to Precharge Command Period register

Address: A070 0034

The Dynamic Memory Active to Precharge Command Period register allows you to program the active to precharge command period,  $t_{RAS}$ . It is recommended that this register be modified during system initialization, or when there are no current or outstanding transactions. Wait until the memory controller is idle, then enter low-power or disabled mode. This value normally is found in SDRAM datasheets as  $t_{RAS}$ .

**Note:** The Dynamic Memory Active to Precharge Command Period register is used for all four dynamic memory chip selects. The worst case value for all chip selects must be programmed.

## Register

Bits	Access	Mnemonic	Description
D31:04	N/A	Reserved	N/A (do not modify)
D03:00	R/W	RAS	<b>Active to precharge command period (<math>t_{RAS}</math>)</b> 0x0–0xE n+1 clock cycles, where the delay is in clk_out cycles. <b>0xF</b> 16 clock cycles (reset value on reset_n)

## Dynamic Memory Self-refresh Exit Time register

Address: A070 0038

The Dynamic Memory Self-refresh Exit Time register allows you to program the self-refresh exit time,  $t_{SREX}$ . It is recommended that this register be modified during system initialization, or when there are no current or outstanding transactions. Wait until the memory controller is idle, then enter low-power or disabled mode. This value normally is found in SDRAM data sheets as  $t_{SREX}$ .

**Note:** The Dynamic Memory Self-refresh Exit Time register is used for all four dynamic memory chip selects. The worst case value for all chip selects must be programmed.

## Register bit assignment

Bits	Access	Mnemonic	Description
D31:04	N/A	Reserved	N/A (do not modify)
D03:00	R/W	SREX	<b>Self-refresh exit time (<math>t_{SREX}</math>)</b> 0x0–0xE n+1 clock cycles, where the delay is in clk_out cycles. <b>0xF</b> 16 clock cycles (reset value on reset_n)

## Dynamic Memory Last Data Out to Active Time register

Address: A070 003C

The Dynamic Memory Last Data Out to Active Time register allows you to program the last-data-out to active command time,  $t_{APR}$ . It is recommended that this register be modified during system initialization, or when there are no current or outstanding transactions. Wait until the memory controller is idle, then enter low-power or disabled mode. This value normally is found in SDRAM datasheets as  $t_{APR}$ .

**Note:** The Dynamic Memory Last Data Out to Active Time register is used for all four dynamic memory chip selects. The worst case value for all chip selects must be programmed.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### Register bit assignment

Bits	Access	Mnemonic	Description
D31:04	N/A	Reserved	N/A (do not modify)
D03:00	R/W	APR	<b>Last-data-out to active command time (<math>t_{APR}</math>)</b> 0x0–0xE n+1 clock cycles, where the delay is in clk_out cycles. <b>0xF</b> 16 clock cycles (reset value on reset_n)

## Dynamic Memory Data-in to Active Command Time register

Address: A070 0040

The Dynamic Memory Data-in to Active Command Time register allows you to program the data-in to active command time,  $t_{DAL}$ . It is recommended that this register be modified during system initialization, or when there are no current or outstanding transactions. Wait until the memory controller is idle, then enter low-power or disabled mode. This value normally is found in SDRAM data sheets as  $t_{DAL}$  or  $t_{APW}$ .

**Note:** The Dynamic Memory Data-in Active Command Time register is used for all four dynamic memory chip selects. The worst case value for all chip selects must be programmed.

### Register

Bits	Access	Mnemonic	Description
D31:04	N/A	Reserved	N/A (do not modify)
D03:00	R/W	DAL	<b>Data-in to active command (<math>t_{DAL}</math> or <math>t_{APW}</math>)</b> 0x0–0xE n+1 clock cycles, where the delay is in clk_out cycles. <b>0xF</b> 15 clock cycles (reset value on reset_n)

## Dynamic Memory Write Recovery Time register

Address: A070 0044

The Dynamic Memory Write Recovery Time register allows you to program the write recovery time,  $t_{WR}$ . It is recommended that this register be modified during system initialization, or when there are no current or outstanding transactions. Wait until the memory controller is idle, then enter low-power or disabled mode. This value normally is found in SDRAM datasheets as  $t_{WR}$ ,  $t_{DPL}$ ,  $t_{RWL}$ , or  $t_{RDL}$ .

**Note:** The Dynamic Memory Write Recovery Time register is used for all four dynamic memory chip selects. The worst case value for all chip selects must be programmed.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## Register bit assignment

Bits	Access	Mnemonic	Description
D31:04	N/A	Reserved	N/A (do not modify)
D03:00	R/W	WR	Write recovery time ( $t_{WR}$ , $t_{DPL}$ , $t_{RWL}$ , or $t_{RDL}$ ) 0x0–0xE n+1 clock cycles, where the delay is in clk_out cycles. <b>0xF</b> 16 clock cycles (reset value on reset_n)

## Dynamic Memory Active to Active Command Period register

Address: A070 0048

The Dynamic Memory Active to Active Command Period register allows you to program the active to active command period,  $t_{RC}$ . It is recommended that this register be modified during system initialization, or when there are no current or outstanding transactions. Wait until the memory controller is idle, then enter low-power or disabled mode. This value normally is found in SDRAM datasheets as  $t_{RC}$ .

**Note:** The Dynamic Memory Active to Active Command period register is used for all four dynamic memory chip selects. The worst case value for all chip selects must be programmed.

## Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## Register bit assignment

Bits	Access	Mnemonic	Description
D31:05	N/A	Reserved	N/A (do not modify)
D04:00	R/W	RC	<b>Active to active command period (<math>t_{RC}</math>)</b> 0x0–0x1E n+1 clock cycles, where the delay is in clk_out cycles. <b>0x1F</b> 32 clock cycles (reset value on reset_n)

## Dynamic Memory Auto Refresh Period register

Address: A070 004C

The Dynamic Memory Auto Refresh Period register allows you to program the auto-refresh period and the auto-refresh to active command period,  $t_{RFC}$ . It is recommended that this register be modified during initialization, or when there are no current or outstanding transactions. Wait until the memory controller is idle, then enter low-power or disabled mode. This value normally is found in SDRAM datasheets as  $t_{RFC}$  or  $t_{RC}$ .

**Note:** The Dynamic Memory Auto Refresh Period register is used for all four dynamic memory chip selects. The worst case value for all chip selects must be programmed.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### Register bit assignment

Bits	Access	Mnemonic	Description
D31:05	N/A	Reserved	N/A (do not modify)
D04:00	R/W	RFC	<b>Auto-refresh period and auto-refresh to active command period</b> 0x0–0x1E n+1 clock cycles, where the delay is in clk_out cycles <b>0x1F</b> 32 clock cycles (reset value on reset_n)

## Dynamic Memory Exit Self-refresh register

Address: A070 0050

The Dynamic Memory Exit Self-refresh register allows you to program the exit self-refresh to active command time,  $t_{XSR}$ . It is recommended that this register be modified during system initialization, or when there are no current or outstanding transactions. Wait until the memory controller is idle, then enter low-power or disabled mode. This value normally is found in SDRAM datasheets as  $t_{XSR}$ .

**Note:** The Dynamic Memory Exit Self-refresh register is used for all four dynamic memory chip selects. The worst case value for all the chip selects must be programmed.

## Register

## Register bit assignment

Bits	Access	Mnemonic	Description
D31:05	N/A	Reserved	N/A (do not modify)
D04:00	R/W	XSR	<b>Exit self-refresh to active time command</b> 0x0–0x1E n+1 clock cycles, where the delay is in clk_out cycles 0x1F 32 clock cycles (reset value on reset_n)

## Dynamic Memory Active Bank A to Active Bank B Time register

Address: A070 0054

The Dynamic Memory Active Bank A to Active Bank B Time register allows you to program the active bank A to active bank B latency,  $t_{RRD}$ . It is recommended that this register be modified during system initialization, or when there are no current or outstanding transactions. Wait until the memory controller is idle, then enter low-power or disabled mode. This value normally is found in SDRAM datasheets as  $t_{RRD}$ .

**Note:** The Dynamic Memory Active Bank A to Active Bank B Time register is used for all four dynamic memory chip selects. The worst case value for all chip selects must be programmed.

## Register

D03:00	R/W	RRD	<b>Active Bank A to Active Bank B</b> 0x0–0xE n+1 clock cycles, where the delay is in clk_out cycles 0xF 16 clock cycles (reset on reset_n)

## Dynamic Memory Load Mode register to Active Command Time register

Address: A070 0058

The Dynamic Memory Load Mode register to Active Command Time register allows you to program the Load Mode register to active command time,  $t_{MRD}$ . It is recommended that this register be modified during system initialization, or when there are no current or outstanding transactions. Wait until the memory controller is idle, then enter low-power or disabled mode. This value normally is found in SDRAM datasheets as  $t_{MRD}$  or  $t_{RSA}$ .

**Note:** The Dynamic Memory Load Mode register to Active Command Time register is used for all four chip selects. The worst case value for all chip selects must be programmed.

## Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## Register bit assignment

Bits	Access	Mnemonic	Description
D31:045	N/A	Reserved	N/A (do not modify)
D03:00	R/W	MRD	<b>Load mode register to Active Command Time</b> 0x0–0xE n+1 clock cycles, where the delay is in clk_out cycles 0xF 16 clock cycles (reset on reset_n)

## Static Memory Extended Wait register

Address: A070 0080

The Static Memory Extended Wait register times long static memory read and write transfers (which are longer than can be supported by the Static Memory Read Delay registers or the Static Memory Write Delay registers) when the EW (extended wait) bit in the related Static Memory Configuration register is enabled.

There is only one Static Memory Extended Wait register, which is used by the relevant static memory chip select if the appropriate EW bit is set in the Static Memory Configuration register.

It is recommended that this register be modified during system initialization, or when there are no current or outstanding transactions. If necessary, however, these control bits can be changed during normal operation.

## Register

## Register bit assignment

Bits	Access	Mnemonic	Description
D31:10	N/A	Reserved	N/A (do not modify)
D09:00	R/W	EXTW	<b>External wait timeout</b> 0x0 16 clock cycles, where the delay is in clk_out cycles 0x1–0x3FF (n=1) x 16 clock cycles

### Example

Static memory read/write time = 16  $\mu$ s

CLK frequency = 50 MHz

This value must be programmed into the Static Memory Extended Wait register:

$$(16 \times 10^{-6} \times 50 \times 10^6 / 16) - 1 = 49$$

## Dynamic Memory Configuration 0–3 registers

Address: A070 0100 / 0120 / 0140 / 0160

Use the Dynamic Memory Configuration 0–3 registers to program the configuration information for the relevant dynamic memory chip select. These registers are usually modified only during system initialization.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1	1	100	00	512 Mb (64Mx8), 4 banks, row length=13, column length=11
1	1	100	01	512 Mb (32Mx16), 4 banks, row length=13, column length=10

### Chip select and memory devices

A chip select can be connected to a single memory device; in this situation, the chip select data bus width is the same as the device width. As an alternative, the chip

select can be connected to a number of external devices. In this situation, the chip select data bus width is the sum of the memory device databus widths.

### Chip select and memory devices: Examples

For a chip select connected to	Select this mapping
32-bit wide memory device	32-bit wide address mapping
16-bit wide memory device	16-bit wide address mapping
4 x 8-bit wide memory devices	32-bit wide address mapping
2 x 8-bit memory devices	16-bit wide address mapping

## Dynamic Memory RAS and CAS Delay 0-3 registers

Address: A070 0104 / 0124 / 0144 / 0164

The Dynamic Memory RAS and CAS Delay 0-3 registers allow you to program the RAS and CAS latencies for the relevant dynamic memory. It is recommended that these registers be modified during system initialization, or when there are no current or outstanding transactions. Wait until the memory controller is idle, then enter low-power or disabled mode.

**Note:** The values programmed into these registers must be consistent with the values used to initialize the SDRAM memory device.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	Access	Mnemonic	Description
D31:10	N/A	Reserved	N/A (do not modify)
D09:08	R/W	CAS	<b>CAS latency</b> 00 Reserved 01 One clock cycle, where the RAS to CAS latency (RAS) and CAS latency (CAS) are defined in clk_out cycles 10 Two clock cycles 11 Three clock cycles (reset value on reset_n)

Bits	Access	Mnemonic	Description
D07:02	N/A	Reserved	<b>N/A (do not modify)</b>
D01:00	R/W	RAS	<b>RAS latency (active to read/write delay)</b> 00 Reserved 01 One clock cycle, where the RAS to CAS latency (RAS) and CAS latency (CAS) are defined in clk_out cycles 10 Two clock cycles 11 Three clock cycles (reset value on reset_n)

## StaticMemory Configuration 0-3 registers

Address: A070 0200 / 0220 / 0240 / 0260

The Static Memory Configuration 0-3 registers configure the static memory configuration. It is recommended that these registers be modified during system initialization, or when there are no current or outstanding transactions. Wait until the memory controller is idle, then enter low-power or disabled mode.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								EW	PB	PC	Reserved	PM	BMODE	MW	

### Register bit assignment

Bits	Access	Mnemonic	Description
D31:21	N/A	Reserved	<b>N/A (do not modify)</b>
D20	R/W	PSMC	<b>Write protect</b> 0 Writes not protected (reset value on reset_n) 1 Write protected
D19	R/W	BSMC	<b>Buffer enable</b> 0 Write buffer disabled (reset value on reset_n) 1 Write buffer enabled Note: This field must always be set to 0 when a peripheral other than SRAM is attached to the static ram chip select.
D18:09	N/A	Reserved	<b>N/A (do not modify)</b>

Bits	Access	Mnemonic	Description
D08	R/W	EW	<p><b>Extended wait</b></p> <p>0 Extended wait disabled (reset value on reset_n)</p> <p>1 Extended wait enabled</p> <p>Extended wait uses the Static Extended Wait register to time both the read and write transfers, rather than the Static Memory Read Delay 0–3 registers and Static Memory Write Delay 0–3 registers. This allows much longer transactions.</p> <p>Extended wait also can be used with the ns_ta_strb signal to allow a slow peripheral to terminate the access. In this case, the Static Memory Extended Wait register can be programmed with the maximum timeout limit. A high value on ns_ta_strb is then used to terminate the access before the maximum timeout occurs.</p> <p>Note: Extended wait and page mode cannot be selected simultaneously.</p>
D07	R/W	PB	<p><b>Byte lane state</b></p> <p>0 For reads, all bits in byte_lane[3:0] are high. For writes, the respective active bits in byte_lane[3:0] are low (reset value for chip select 0, 2, and 3 on reset_n).</p> <p>1 For reads, the respective active bits in byte_lane[3:0] are low. For writes, the respective active bits in byte_lane[3:0] are low.</p> <p>Note: Setting this bit to 0 disables the write enable signal. WE_n will always be set to 1 (that is, you must use byte lane select signals).</p> <p>The byte lane state bit (PB) enables different types of memory to be connected. For byte-wide static memories, the byte_lane[3:0] signal from the memory controller is usually connected to WE_n (write enable). In this case, for reads, all byte_lane[3:0] bits must be high, which means that the byte lane state bit must be low.</p> <p>16-bit wide static memory devices usually have the byte_lane[3:0] signals connected to the nUB and nLB (upper byte and lower byte) signals in the static memory. In this case, a write to a particular byte must assert the appropriate nUB or nLB signal low. For reads, all nUB and nLB signals must be asserted low so the bus is driven. In this case, the byte lane state must be high.</p>
D06	R/W	PC	<p><b>Chip select polarity</b></p> <p>0 Active low chip select</p> <p>1 Active high chip select</p>
D05:04	N/A	Reserved	N/A (do not modify)

Bits	Access	Mnemonic	Description
D03	R/W	PM	<b>Page mode</b> 0 Disabled (reset on reset_n) 1 Async page mode enabled (page length four) In page mode, the memory controller can burst up to four external accesses. Devices with asynchronous page mode burst four or higher are supported. Asynchronous page mode burst two devices are not supported and must be accessed normally.
D02	R/W	BMODE	<b>Burst mode</b> Allows the static output enable signal to toggle during bursts. 0 Do not toggle output enable during bursts 1 Toggle output enable during bursts
D01:00	R/W	MW	<b>Memory width</b> 00 8 bit (reset value for chip select 0, 2, and 3 on reset_n) 01 16 bit 10 32 bit 11 Reserved The value of the chip select 1 memory width field on power-on reset (reset_n) is determined by the gpio_a[0], addr[23] signal. This value can be overridden by software. Note: For chip select 1, the value of the gpio_a[0], addr[23] signal is reflected in this field. When programmed, this register reflects the last value written into it.

**Note:** Synchronous burst mode memory devices are not supported.

## StaticMemory Write Enable Delay 0-3 registers

Address: A070 0204 / 0224 / 0244 / 0264

The Static Memory Write Enable Delay 0-3 registers allow you to program the delay from the chip select to the write enable assertion. The Static Memory Write Enable Delay register is used in conjunction with the Static Memory Write Delay registers, to control the width of the write enable signals. It is recommended that these registers be modified during system initialization, or when there are no current or outstanding transactions. Wait until the memory controller is idle, then enter low-power or disabled mode.

## Register

Bits	Access	Mnemonic	Description
D31:04	N/A	Reserved	N/A (do not modify)
D03:00	R/W	WWEN	<b>Wait write enable (WAITWEN)</b> 0000 One clk_out cycle delay between assertion of chip select and write enable (reset value on reset_n). 0001–1111 (n+1) clk_out cycle delay, where the delay is (WAITWEN+1) x t <sub>clk_out</sub> Delay from chip select assertion to write enable.

## Static Memory Output Enable Delay 0-3 registers

Address: A070 0208 / 0228 / 0248 / 0268

The Static Memory Output Enable Delay 0–3 registers allow you to program the delay from the chip select or address change, whichever is later, to the output enable assertion. The Static Memory Output Enable Delay register is used in conjunction with the Static Memory Read Delay registers, to control the width of the output enable signals. It is recommended that these registers be modified during system initialization, or when there are no current or outstanding transactions. Wait until the memory controller is idle, then enter low-power or disabled mode.

## Register

D03:00	R/W	WOEN	<b>Wait output enable (WAITOEN)</b> 0000 No delay (reset value on reset_n). 0001–1111n cycle delay, where the delay is $\text{WAITOEN} \times t_{\text{clk\_out}}$ Delay from chip select assertion to output enable.

## Static Memory Read Delay 0-3 registers

Address: A070 020C / 022C / 024C / 026C

The Static Memory Read Delay 0-3 registers allow you to program the delay from the chip select to the read access. It is recommended that these registers be modified during system initialization, or when there are no current or outstanding transactions. Wait until the memory controller is idle, then enter low-power or disabled mode. These registers are not used if the extended wait bit is set in the related Static Memory Configuration register.

All values are in nanoseconds</p>

## StaticMemory Page Mode Read Delay 0-3 registers

Address: A070 0210 / 0230 / 0250 / 0270

The Static Memory Page Mode Read Delay 0-3 registers allow you to program the delay for asynchronous page mode sequential accesses. These registers control the overall period for the read cycle. It is recommended that these registers be modified during system initialization, or when there are no current or outstanding transactions. Wait until the memory controller is idle, then enter low-power or disabled mode.

## Register

For asynchronous page mode read for sequential reads, the wait state time for page mode accesses after the first read is (WAITPAGE+1) x t <sub>clk_out</sub> 11111 32 clk_out cycles read access time (reset value on reset_n) Number of wait states for asynchronous page mode read accesses after the first read.

## Static Memory Write Delay 0-3 registers

Address: A070 0214 / 0234 / 0254 / 0274

The Static Memory Write Delay 0-3 registers allow you to program the delay from the chip select to the write access. These registers control the overall period for the write cycle. It is recommended that these registers be modified during system initialization, or when there are no current or outstanding transactions. Wait until the memory controller is idle, then enter low-power or disabled mode. These registers are not used if the extended wait bit is enabled in the related Static Memory Configuration register.

### Register

### Register bit assignment

Bits	Access	Mnemonic	Description
D31:05	N/A	Reserved	N/A (do not modify)
D04:00	R/W	WTWR	<b>Write wait states (WAITWR)</b> 00000–11110 (n+2) clk_out cycle write access time. The wait state time for write accesses after the first read is WAITWR (n+2) x t <sub>clk_out</sub> 11111 332 clk_out cycle write access time (reset value on reset_n) SRAM wait state time for write accesses after the first read.

## StaticMemory Turn Round Delay 0-3 registers

Address: A070 0218 / 0238 / 0258 / 0278

The Static Memory Turn Round Delay 0-3 registers allow you to program the number of bus turnaround cycles. It is recommended that these registers be modified during system initialization, or when there are no current or outstanding transactions. Wait until the memory controller is idle, then enter low-power or disabled mode.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												WTTN			

### Register bit assignment

Bits	Access	Mnemonic	Description
D31:04	N/A	Reserved	N/A (do not modify)
D03:00	R/W	WTTN	<b>Bus turnaround cycles (WAITTURN)</b> 00000–11110 (n+1) clk_out turnaround cycles, where bus turnaround time is (WAITTURN+1) × t <sub>clk_out</sub> 1111 16 clk_out turnaround cycles (reset value on reset_n).

To prevent bus contention on the external memory databus, the WAITTURN field controls the number of bus turnaround cycles added between static memory read and write accesses.

The WAITTURN field also controls the number of turnaround cycles between static memory and dynamic memory accesses.

*StaticMemory Turn Round Delay 0–3 registers*

# Ethernet Communication Module

## C H A P T E R 6

**T**he Ethernet Communication module consists of an Ethernet Media Access Controller (MAC) and Ethernet front-end module. The Ethernet MAC interfaces to an external PHY through the industry-standard interface: Media Independent Interface (MII). The Ethernet front-end module provides all of the control functions to the MAC.

### Features

The Ethernet MAC module provides the following:

- Station address logic (SAL)
- Statistics module
- Interface to MII (Media Independent Interface) PHY

The Ethernet front-end module does the following:

- Provides control functions to the MAC
- Buffers and filters the frames received from the MAC
- Pumps transmit data into the MAC
- Moves frames between the MAC and the system memory
- Reports transmit and receive status to the host

### Common acronyms

RX\_RD = Receive read

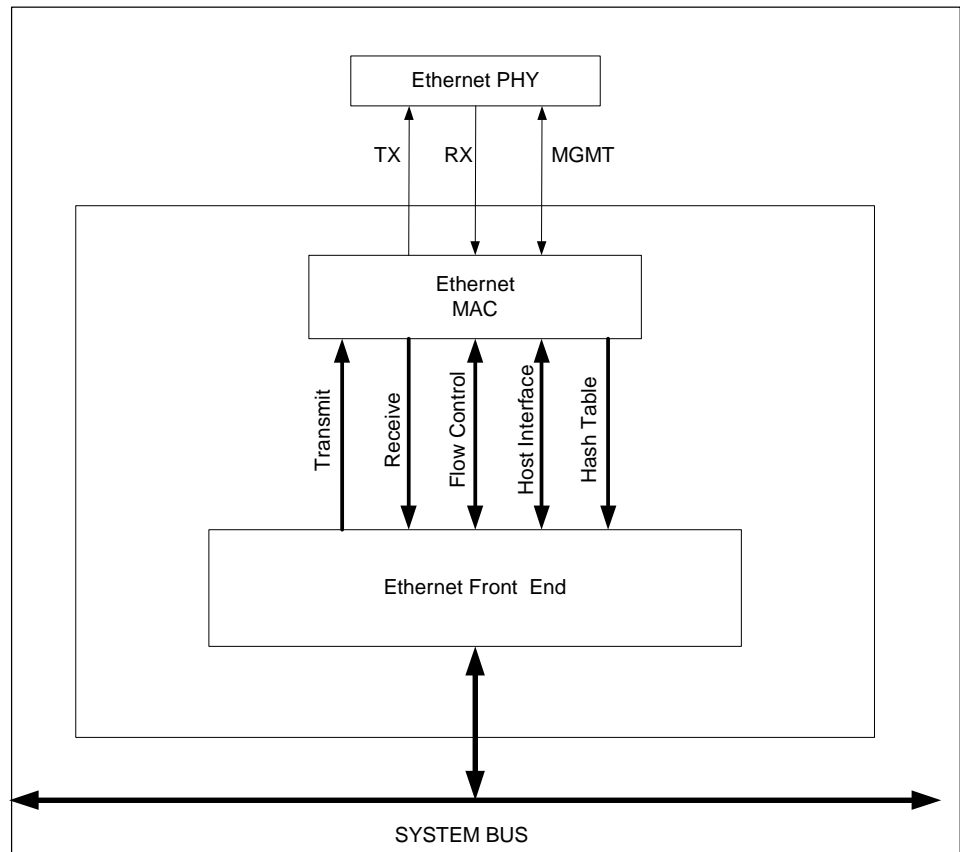

RX\_WR = Receive write

TX\_RD = Transmit read

TX\_WR = Transmit write

## Ethernet communications module

## Ethernet MAC

The Ethernet MAC includes a full function 10/100 Mbps Media Access Controller (MAC), station address filtering logic (SAL), statistic collection module (STAT), and MII.

## MAC module block diagram

## MAC module features

Feature	Description
MAC Core	<b>10/100 megabit Media Access Controller</b> Performs the CSMA/CD function. <ul style="list-style-type: none"> <li>■ MCS: MAC control sublayer</li> <li>■ TFUN: Transmit function</li> <li>■ RFUN: Receive function</li> </ul>
HOST	<b>Host interface</b> Provides an interface for control and configuration.
CLK & Reset	<b>Clocks &amp; resets</b> Provides a central location for clock trees and reset logic.
MIIM	<b>MII management</b> Provides control/status path to MII PHYs.
STAT	<b>Statistics module</b> Counts and saves Ethernet statistics.

Feature	Description
SAL	<b>Station address logic</b> Performs destination address filtering.
MII	<b>Media Independent Interface</b> Provides the interface from the MAC core to a PHY that supports the MII (as described in the IEEE 802.3 standard).

### PHY interface mappings

This table shows how the different PHY interfaces are mapped to the external IO.

External IO	MII
RXD[3]	RXD[3]
RXD[2]	RXD[2]
RXD[1]	RXD[1]
RXD[0]	RXD[0]
RX_DV	RX_DV

TXD[3]	TXD[3]
TXD[2]	TXD[2]
TXD[1]	TXD[1]
TXD[0]	TXD[0]
TX_EN	TX_EN
TX_ER	TX_ER
TX_CLK	TX_CLK
CRS	CRS
COL	COL
MDC	MDC
MDIO	MDIO

## Station address logic (SAL)

The station address logic module examines the destination address field of incoming frames, and filters the frames before they are stored in the Ethernet front-end

module. The filtering options, listed next, are programmed in the Station Address Filter register (see page 301).

- Accept frames to destination address programmed in the SA1, SA2, and SA3 registers (Station Address registers, beginning on page 300)
- Accept all frames
- Accept all multicast frames
- Accept all multicast frames using HT1 and HT2 registers. See “Sample hash table code,” on page 334)
- Accept all broadcast frames

The filtering conditions are independent of each other; for example, the Station Address Logic register can be configured to accept all broadcast frames, and frames to the programmed destination address.

### MAC receiver

- The MAC receiver provides the station address logic with a 6-bit CRC value that is the upper 6 bits of a 32-bit CRC calculation performed on the 48-bit multicast destination address. This 6-bit value addresses the 64-bit multicast hash table created in the HT1 and HT2 registers. See “Sample hash table code,” on page 334)
- If the current receive frame is a multicast frame and the 6-bit CRC addresses a bit in the hash table that is set to 1, the receive frame is accepted; otherwise, the frame is rejected. See “Sample hash table code,” on page 334) for sample C code to calculate hash table entries.

## Statistics module

The Statistics module counts and saves Ethernet statistics in several counters (see “Statistics registers” on page 303).

The Ethernet General Control Register #2 contains three statistics module configuration bits:

- **AUTOZ.** Enable statistics counter clear on read.
- **CLRCNT.** Clear statistics counters.
- **STEN.** Enable statistics counters.

If any of the counters roll over, an associated carry bit is set in the Carry 1 (CAR1) or Carry 2 (CAR2) registers (see “General Statistics registers address map,” beginning on page 310). Any statistics counter overflow can cause the STOVFL bit in the Ethernet Interrupt Status register (see page 317) to be set if its associated mask bit is not set in Carry Mask Register 1 or Carry Mask Register 2.

The counters support a *clear on read* capability that is enabled when AUTOZ is set to 1 in the Ethernet General Control Register #2.

## Ethernet front-end module

### Ethernet front-end module (EFE)

The EFE module includes a set of control and status registers, a receive packet processor, and a transmit packet processor. On one side, the Ethernet front end interfaces to the MAC and provides all control and status signals required by the MAC. On the other side, the Ethernet front end interfaces to the system.

### Receive packet processor

The receive packet processor accepts good Ethernet frames (for example, valid checksum and size) from the Ethernet front end and commits them to external system memory. Bad frames (for example, invalid checksum or code violation) and frames with unacceptable destination addresses are discarded.

The 2K byte RX\_FIFO allows the entire Ethernet frame to be buffered while the receive byte count is analyzed. The receive byte count is analyzed by the receive packet processor to select the optimum-sized buffer for transferring the received frame to system memory. The processor can use one of four different-sized receive buffers in system memory.

### Transmit packet processor

The transmit packet processor transfers frames constructed in system memory to the Ethernet MAC. The software initializes a buffer descriptor table in a local RAM that points the transmit packet processor to the various frame segments in system memory. The 256-byte TX\_FIFO decouples the data transfer to the Ethernet MAC from the AHB bus fill rate.

## Receive packet processor

As a frame is received from the Ethernet MAC, it is stored in the receive data FIFO. At the end of the frame, an accept/reject decision is made based on several conditions. If the packet is rejected, it is flushed from the receive data FIFO.

If a frame is accepted, status signals from the MAC, including the receive size of the frame, are stored in a separate 32-entry receive status FIFO; the RX\_RD logic is notified that a good frame is in the FIFO.

If the RX\_WR logic tries to write to a full receive data FIFO anytime during the frame, it flushes the frame from the receive data FIFO and sets RXOVFL\_DATA (RX data FIFO overflowed) in the Ethernet Interrupt Status register. For proper operation, reset the receive packet processor using the ERX bit in the Ethernet General Control Register #1 when this condition occurs. If the RX\_WR logic tries to write a full receive status FIFO at the end of the frame, the RX\_WR logic flushes the frame from the receive data FIFO and sets RXOVFL\_STAT (RX status FIFO overflowed) in the Ethernet Interrupt Status register.

### Power down mode

The RX\_WR logic supports the processor system power down and recovery functionality. In this mode, the RX clock to the MAC and the RX\_WR logic are still active, but the clock to the RX\_RD and AHB interface is disabled. This allows frames to be received and written into the receive FIFO, but the frame remains in the FIFO until the system wakes up. Normal frame filtering is still performed.

When a qualified frame is inserted into the receive FIFO, the receive packet processor notifies the system power controller, which performs the *wake up* sequence. The frame remains in the receive FIFO until the system wakes up.

### Transferring a frame to system memory

The RX\_RD logic manages the transfer of a frame in the RX\_FIFO to system memory. The transfer is enabled by setting the ERXDMA (enable receive DMA) bit in Ethernet General Control Register #1.

Transferring a frame in the receive FIFO to system memory begins when the RX\_WR logic notifies the RX\_RD logic that a good frame is in the receive FIFO. Frames are transferred to system memory using up to four rings (that is, 1, 2, or 3 rings can also be used) of buffer descriptors that point to buffers in system memory. The maximum frame size that each ring can accept is programmable. The first thing the RX\_RD logic does, then, is analyze the frame length in the receive status FIFO to determine which buffer descriptor to use.

The RX\_RD logic goes through the four buffer descriptors looking for the optimum buffer size. It searches the enabled descriptors starting with A, then B, C, and finally D; any pools that are full (that is, the F bit is set in the buffer descriptor) are skipped. The search stops as soon as the logic encounters an available buffer that is large enough to hold the entire receive frame.

The pointers to the first buffer descriptor in each of the four pools are found in the related Buffer Descriptor Pointer register (RXAPTR, RXBPTR, RXCPTR, RXDPTR). Pointers to subsequent buffer descriptors are generated by adding an offset of 0x10 from this pointer for each additional buffer used.

### Receive buffer descriptor format

	31	30	29	28		16	15		0
OFFSET + 0	Source Address								
OFFSET + 4	Buffer Length (11 lower bits used)								
OFFSET + 8	Destination Address (not used)								
OFFSET + C	W	I	E	F	Reserved		Status		

### Receive buffer descriptor format description

The current buffer descriptor for each pool is kept in local registers. The current buffer descriptor registers are initialized to the buffer descriptors pointed to by the Buffer Descriptor Pointer registers, by setting the ERXINIT (enable initialization of RX buffer descriptor registers) bit in Ethernet General Control Register #1. The initialization process is complete when RXINIT (RX initialization complete) is set in the Ethernet General Status register. At the end of a frame, the next buffer descriptor for the ring just used is read from system memory and stored in the registers internal to the RX\_RD logic.

## Receive buffer descriptor field definitions

Field	Description
W	<p>WRAP bit, which, when set, tells the RX_RD logic that this is the last buffer descriptor in the ring. In this situation, the next buffer descriptor is found using the appropriate Buffer Descriptor Pointer register.</p> <p>When the WRAP bit is not set, the next buffer descriptor is found using an offset of 0x10 from the current buffer descriptor pointer.</p>
I	When set, tells the RX_RD logic to set RXBUFC in the Ethernet Interrupt Status register after the frame has been transferred to system memory.
E	<p>ENABLE bit, which, when set, tells the RX_RD logic that this buffer descriptor is enabled. When a new frame is received, pools that do not have the ENABLE bit set in their next buffer descriptor are skipped when deciding in which pool to put the frame.</p> <p>The receive processor can use up to four different-sized receive buffers in system memory.</p> <p><b>Note:</b></p> <p>To enable a pool that is currently disabled, change the ENABLE bit from 0 to 1 and reinitialize the buffer descriptors pointed to by the Buffer Descriptor Pointer register:</p> <ol style="list-style-type: none"> <li>1 Set the ERXINIT bit in the Ethernet General Control Register 1.</li> <li>7 Wait for RXINIT to be set in the Ethernet General Status register.</li> </ol> <p>Change the ENABLE bit only while the receive packet processor is idle.</p>
Buffer pointer	32-bit pointer to the start of the buffer in system memory. This pointer must be aligned on a 32-bit boundary.
Status	Lower 16 bits of the Ethernet Receive Status register. The status is taken from the receive status FIFO and added to the buffer descriptor after the last word of the frame is written to system memory.
F	When set, indicates the buffer is full. The RX_RD logic sets this bit after filling a buffer. The system software clears this bit, as required, to free the buffer for future use. When a new frame is received, pools that have the F bit set in their next buffer descriptor are skipped when deciding in which pool to put the frame.
Buffer length	<p>This is a dual use field:</p> <ul style="list-style-type: none"> <li>■ When the buffer descriptor is read from system memory, buffer length indicates the maximum sized frame, in bytes, that can be stored in this buffer ring.</li> <li>■ When the RX_RD logic writes the descriptor back from the receive status FIFO into system memory at the end of the frame, the buffer length is the actual frame length, in bytes. Only the lower 11 bits of this field are valid, since the maximum legal frame size for Ethernet is 1522 bytes.</li> </ul>

## Transmit packet processor

Transmit frames are transferred from system memory to the transmit packet processor into a 256-byte TX\_FIFO. Because various parts of the transmit frame can

reside in different buffers in system memory, several buffer descriptors can be used to transfer the frame.

Transmit buffer descriptor format

All buffer descriptors (that is, up to 64) are found in a local TX buffer descriptor RAM. This is the transmit buffer descriptor format.

	31	30	29	28		16	15		0
OFFSET + 0	Source Address								
OFFSET + 4	Buffer Length (11-bits used)								
OFFSET + 8	Destination Address (not used)								
OFFSET + C	W	I	L	F	Reserved		Status		

Transmit buffer descriptor field definitions

Field	Description
W	<p>WRAP bit, which, when set, tells the TX_WR logic that this is the last buffer descriptor within the continuous list of descriptors in the TX buffer descriptor RAM. The next buffer descriptor is found using the initial buffer descriptor pointer in the TX Buffer Descriptor Pointer register (TXPTR).</p> <p>When the WRAP bit is not set, the next buffer descriptor is located at the next entry in the TX buffer descriptor RAM.</p>
I	When set, tells the TX_WR logic to set TXBUFC in the Ethernet Interrupt Status register when the buffer is closed due to a normal channel completion.
Buffer pointer	32-bit pointer to the start of the buffer in system memory. This pointer can be aligned on any byte of a 32-bit word.
Status	Lower 16 bits of the Ethernet Transmit Status register. The status is returned from the Ethernet MAC at the end of the frame and written into the last buffer descriptor of the frame.
L	When set, tells the TX_WR logic that this buffer descriptor is the last descriptor that completes an entire frame. This bit allows multiple descriptors to be chained together to make up a frame.

Field	Description
F	<p>When set, indicates the buffer is full. The TX_WR logic clears this bit after emptying a buffer. The system software sets this bit as required, to signal that the buffer is ready for transmission. If the TX_WR logic detects that this bit is not set when the buffer descriptor is read, it does one of two things:</p> <ul style="list-style-type: none"> <li>■ If a frame is not in progress, the TX_WR logic sets the TXIDLE bit in the Ethernet Interrupt Status register.</li> <li>■ If a frame is in progress, the TXBUFNR bit in the Ethernet Interrupt Status register is set.</li> </ul> <p>In either case, the TX_WR logic stops processing frames until TCLER (clear transmit logic) in Ethernet General Control Register #2 is toggled from low to high.</p> <p>TXBUFNR is set only for frames that consist of multiple buffer descriptors and contain a descriptor — <i>not</i> the first descriptor — that does not have the F bit set after frame transmission has begun.</p>
Buffer length	<p>This is a dual use field:</p> <ul style="list-style-type: none"> <li>■ When the buffer descriptor is read from the TX buffer descriptor RAM, buffer length indicates the length of the buffer, in bytes. The TX_WR logic uses this information to identify the end of the buffer. For proper operation of the TX_WR logic, all transmit frames must be at least 34 bytes in length.</li> <li>■ When the TX_WR logic updates the buffer descriptor at the end of the frame, it writes the length of the frame, in bytes, into this field for the last buffer descriptor of the frame.</li> </ul> <p>If the MAC is configured to add the CRC to the frame (that is, CRCEN in MAC Configuration Register #2 is set to 1), this field will include the four bytes of CRC. This field is set to 0x000 for jumbo frames that are aborted. Only the lower 11 bits of this field are valid, since the maximum legal frame size for Ethernet is 1522 bytes.</p>

## Transmitting a frame

Setting the EXTDMA (enable transmit DMA) bit in Ethernet General Control Register #1 starts the transfer of transmit frames from the system memory to the TX\_FIFO. The TX\_WR logic reads the first buffer descriptor in the TX buffer descriptor RAM.

- If the F bit is set, it transfers data from system memory to the TX\_FIFO using the buffer pointer as the starting point. This process continues until the end of the buffer is reached. The address for each subsequent read of the buffer is incremented by 32 bytes (that is, 0x20). The buffer length field in the buffer descriptor is decremented by this same value, each transfer, to identify when the end of the buffer is reached.
- If the L field in the buffer descriptor is 0, the next buffer descriptor in the RAM continues the frame transfer until the L field in the current buffer descriptor is 1. This identifies the current buffer as the last buffer of a transmit frame.

After the entire frame has been written to the TX\_FIFO, the TX\_WR logic waits for a signal from the TX\_RD logic indicating that frame transmission has completed at the MAC. The TX\_WR logic updates the buffer length, status, and F fields of the current buffer descriptor (that is, the last buffer descriptor for the frame) in the TX buffer descriptor RAM when the signal is received.

The TX\_WR logic examines the status received from the MAC after it has transmitted the frame.

**Frame  
transmitted  
successfully**

If the frame was transmitted successfully, the TX\_WR logic sets TXDONE (frame transmission complete) in the Ethernet Interrupt Status register and reads the next buffer descriptor. If a new frame is available (that is, the F bit is set), the TX\_WR starts transferring the frame. If a new frame is not available, the TX\_WR logic sets the TXIDLE (TX\_WR logic has no frame to transmit) bit in the Ethernet Interrupt Status register and waits for the software to toggle TCLER (clear transmit logic), in Ethernet General Control Register #2, from low to high to resume processing. When TCLER is toggled, transmission starts again with the buffer descriptor pointed to by the Transmit Recover Buffer Descriptor Pointer register. Software should update this register before toggling TCLER.

**Frame  
transmitted  
unsuccessfully**

If the TX\_WR logic detects that the frame was aborted or had an error, the logic updates the current buffer descriptor as described in the previous paragraph. If the frame was aborted before the last buffer descriptor of the frame was accessed, the result is a situation in which the status field of a buffer descriptor, which is not the last buffer descriptor in a frame, has a non-zero value. The TX\_WR logic stops processing frames until TCLER (clear transmit logic) in Ethernet General Control Register #2 is toggled from low to high to resume processing. The TX\_WR logic also sets TXERR (last frame not transmitted successfully) in the Ethernet Interrupt Status register and loads the TX buffer descriptor RAM address of the current buffer descriptor in the TX Error Buffer Descriptor Pointer register (see page 320). This allows identification of the frame that was not transmitted successfully. As part of the recovery procedure, software must read the TX Error Buffer Descriptor Pointer register and then write the 8-bit address of the buffer descriptor to resume transmission into the TX Recover Buffer Descriptor Pointer register.

**Transmitting a  
frame to the  
Ethernet MAC**

The TX\_RD logic is responsible for reading data from the TX\_FIFO and sending it to the Ethernet MAC. The logic does not begin reading a new frame until the TX\_FIFO is full. This scheme decouples the data transfer to the Ethernet MAC from the fill rate from the AHB bus. For short frames that are less than 256 bytes, the transmit process begins when the end-of-frame signal is received from the TX\_WR logic.

When the MAC completes a frame transmission, it returns status bits that are stored in the Ethernet Transmit Status register (see page 283) and written into the status field of the current buffer descriptor.

**Ethernet  
underrun**

An Ethernet underrun can only occur due to the following programming errors:

- Insufficient bandwidth is assigned to the Ethernet transmitter.

- A packet consisting of multiple, linked buffer descriptors does not have the F bit set in any of the non-first buffer descriptors.

When an underrun occurs, it is also possible for the Ethernet transmitter to send out a corrupted packet with a good Ethernet CRC if the MAC is configured to add the CRC to the frame (that is, CRCEN in MAC Configuration Register #2 is set to 1).

## Ethernet slave interface

The AHB slave interface supports only single 32-bit transfers. The slave interface also supports limiting CSR and RAM accesses to CPU “privileged mode” accesses. Use the internal register access mode bit 0 in the Miscellaneous System Configuration register to set access accordingly (see “Miscellaneous System Configuration and Status register,” beginning on page 183).

The slave also generates an AHB ERROR if the address is not aligned on a 32-bit boundary, and the misaligned bus address response mode is set in the Miscellaneous System Configuration register. In addition, accesses to non-existent addresses result in an AHB ERROR response.

## Interrupts

Separate RX and TX interrupts are provided back to the system.

### Interrupt sources

This table shows all interrupt sources and the interrupts to which they are assigned.

Interrupt condition	Description	Interrupt
RX data FIFO overflow	RX data FIFO overflowed. For proper operation, reset the receive packet processor using the ERX bit in the Ethernet General Control Register #1 when this condition occurs.	RX
RX status FIFO overflow	RX status overflowed.	RX
Receive buffer closed	I bit set in receive buffer descriptor and buffer closed.	RX
Receive complete (Pool A)	Complete receive frame stored in pool A of system memory.	RX
Receive complete (Pool B)	Complete receive frame stored in pool B of system memory.	RX
Receive complete (Pool C)	Complete receive frame stored in pool C of system memory.	RX
Receive complete (Pool D)	Complete receive frame stored in pool D of system memory.	RX

Interrupt condition	Description	Interrupt
No receive buffers	No buffer is available for this frame because all 4 buffer rings are disabled, full, or no available buffer is big enough for the frame.	RX
Receive buffers full	No buffer is available for this frame because all 4 buffers are disabled or full.	RX
RX buffer ready	Frame available in RX_FIFO. (Used for diagnostics.)	RX
Statistics counter overflow	One of the statistics counters has overflowed. Individual counters can be masked using the CAM1 and CAM2 registers.	TX
Transmit buffer closed	I bit set in Transmit buffer descriptor and buffer closed.	TX
Transmit buffer not ready	F bit not set in transmit buffer descriptor when read from TX buffer descriptor RAM, for a frame in progress.	TX
Transmit complete	Frame transmission complete.	TX
TXERR	Frame not transmitted successfully.	TX
TXIDLE	TX_WR logic in idle mode because there are no frames to send.	TX

### Status bits

The status bits for all interrupts are available in the Ethernet Interrupt Status register, and the associated enables are available in the Ethernet Interrupt Enable register. Each interrupt status bit is cleared by writing a 1 to it.

## Resets

This table provides a summary of all resets used for the Ethernet front-end and MAC, as well as the modules the resets control.

Bit field	Register	Active state	Default state	Modules reset
ERX	Ethernet General Control Register #1	0	0	RX_RD, RX_WR
ETX	Ethernet General Control Register #1	0	0	TX_RD, TX_WR
MAC_HRST	Ethernet General Control Register #1	1	0	MAC, STAT, RX_WR, TX_RD, programmable registers in Station Address Logic
SRST	MAC1	1	1	MAC (except programmable registers), Station Address Logic (except programmable registers), RX_WR, TX_RD
RPERFUN	MAC1	1	0	MAC RX logic
RPEMCST	MAC1	1	0	MAC PEMCS (TX side)

Bit field	Register	Active state	Default state	Modules reset
RPETFUN	MAC1	1	0	MAC TX logic
MIIM	MII Management Configuration register	1	0	MAC MIIM logic

## Multicast address filtering

The RX-WR logic contains a programmable 8-entry multicast address filter that provides more restrictive filtering than that available in the MAC using the SAL. Only multicast addresses that match those programmed into the filter will be accepted.

### Filter entries

Each entry in the filter consists of a 48-bit destination address, an enable bit, and a 48-bit mask. The mask contains a 1 in each bit position of the address that is used in the address filter.; this is used to extend the range of each entry.

### Multicast address filter registers

Register	Description
MFILTL [7:0]	Lower 32 bits of multicast address
MFILTH [7:0]	Upper 16 bits of multicast address
MCMSKL	Lower 32 bits of multicast address mask
MCMSKH [7:0]	Upper 16 bits of multicast address
MFILTEN	Per-entry enable bits

### Multicast address filtering example 1

To accept only multicast packets with destination address 0x01\_00\_5E\_00\_00\_00 using entry 0, the registers are set as shown:

Register	Value	Function
MFILTEN	0x1	Enable entry 0
MFILTL0	0x5E_00_00_00	Lower 32 bits of multicast address
MFILTH0	0x01_00	Upper 16 bits of multicast address
MCMSKL0	0xFFFF_FFFF	Include all of the lower 32 bits of the multicast address in the comparison.
MCMSKH0	0xFFFF	Include all of the upper 16 bits of the multicast address in the comparison

### Multicast address filtering example 2

To accept multicast packets with destination addresses in the range of 0x01\_00\_5E\_00\_00\_00 to 0x01\_00\_5E\_00\_00\_0f using entry 4, the registers are set as shown:

Register	Value	Function
MFILTEN	0x10	Enable entry 4
MFILTL4	0x5E_00_00_00	Lower 32 bits of multicast address
MFILTH4	0x01_00	Upper 16 bits of multicast address
MCMSKL4	0xFFFF_FFF0	Include only bits [31:04] of the lower 32 bits of the multicast address in the comparison.
MCMSKH4	0xFFFF	Include all of the upper 16 bits of the multicast address in the comparison

### Notes

- If any of the address filter entries are enabled, the SAL must be set up to accept all multicast packets by setting the PRM bit in the Station Address Filter register.
- Runt packets that are less than 6 bytes, and therefore do not have a valid destination address, are automatically discarded by the multicast address filtering logic.

## Clock synchronization

The multicast filtering logic resides in the RX CLK domain, but all of the registers are controlled in the AHB clock domain. To provide traditional dual-rank clock synchronization flops for each bit of the five Multicast Address Filter registers consumes a large amount of gates. Therefore, the logic is designed such that only the MFILTEN register bits are synchronized and when these bits are cleared, changes in the other register values are not seen at the input of any internal flops in the RX CLK domain.

### Writing to other registers

Use these steps to dynamically write to any of the other Multicast Address Filter registers:

- 1 Clear the enable bit in the MFILTEN register for the address filter you want to change.
- 2 Update the address filter registers for the disabled filter.
- 3 Set the enable bit for the address filter that was just changed.

If the address filters are changed only when the RX\_WR logic is reset or not processing frames, as recommended, the address filter registers can be updated without using this procedure.

## Ethernet Control and Status registers

All configuration registers must be accessed as 32-bit words and as single accesses only. Bursting is not allowed.

### Register address filter

Address	Register	Description
A060 0000	EGCR1	Ethernet General Control Register #1
A060 0004	EGCR2	Ethernet General Control Register #2
A060 0008	EGSR	Ethernet General Status register

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31	R/W	ERX	0	<b>Enable RX packet processing</b> 0 Reset RX 1 Enable RX Used as a soft reset for the RX. When cleared, resets all logic in the RX and flushes the FIFO. The ERX bit must be set active high to allow data to be received from the MAC receiver.
D30	R/W	ERXDMA	0	<b>Enable receive DMA</b> 0 Disable receive DMA data request (use to stall receiver) 1 Enable receive DMA data request Must be set active high to allow the RX_RD logic to request the AHB bus to DMA receive frames into system memory. Set this bit to zero to temporarily stall the receive side Ethernet DMA. The RX_RD logic stalls on frame boundaries.
D29	N/A	Reserved	N/A	N/A
D28	R/W	ERXSHT	0	<b>Accept short (&lt;64) receive frames</b> 0 Do not accept short frames 1 Accept short frames When set, allows frames that are smaller than 64 bytes to be accepted by the RX_WR logic. ERXSHT is typically set for debugging only.
D27:24	R/W	Not used	0	Always write as 0.
D23	R/W	ETX	0	<b>Enable TX packet processing</b> 0 Reset TX 1 Enable TX Used as a soft reset for the TX. When cleared resets all logic in the TX and flushes the FIFOs. ETX must be set active high to allow data to be sent to the MAC and to allow processor access to the TX buffer descriptor RAM.

Bits	Access	Mnemonic	Reset	Description
D22	R/W	ETXDMA	0	<p><b>Enable transmit DMA</b></p> <p>0    Disable transmit DMA data request (use to stall transmitter)</p> <p>1    Enable transmit DMA data request</p> <p>Must be set active high to allow the transmit packet processor to issue transmit data requests to the AHB interface.</p> <p>Set this bit to 0 to temporarily stall frame transmission, which always stalls at the completion of the current frame. The 8-bit address of the next buffer descriptor to be read in the TX buffer descriptor RAM is loaded into the TXSPTR register when the transmit process ends.</p> <p>If the transmit packet processor already is stalled and waiting for TCLER, clearing ETXDMA will not take effect until TCLER has been toggled.</p> <p>This bit generally should be set after the Ethernet transmit parameters (for example, buffer pointer descriptor) are programmed into the transmit packet processor.</p>
D21	R/W	Not used	1	Always write as 1.
D20	R/W	Not used	0	Always write as 0.
D19	R/W	ERXINIT	0	<p><b>Enable initialization of RX buffer descriptors</b></p> <p>0    Do not initialize</p> <p>1    Initialize</p> <p>When set, causes the RX_RD logic to initialize the internal buffer descriptor registers for each of the four pools from the buffer descriptors pointed to by RXAPTR, RXBPTR, RXCPTR, and RXDPTR. This is done as part of the RX initialization process. RXINIT is set in the Ethernet General Status register when the initialization process is complete, and ERXINIT must be cleared before enabling frame reception from the MAC.</p> <p>The delay from ERXINIT set to RXINIT set is less than five microseconds.</p>
D18:13	N/A	Reserved	N/A	N/A
D12	R/W	Not used	0	Always write as 0.
D11	R/W	RXSHFT	0	<p>Shift RX data</p> <p>0    Standard receive format. No padding bytes added before receive frame data</p> <p>1    The receiver inserts 2 bytes of padding before the first byte of the receive data, to create longword alignment of the payload.</p>

Bits	Access	Mnemonic	Reset	Description
D10	R/W	RXALIGN	0	<b>Align RX data</b> 0 Standard receive format. The data block immediately follows the 14-byte header block. 1 The receiver inserts a 2-byte padding between the 14-byte header and the data block, causing longword alignment for both the header and data blocks.
D09	R/W	MAC_HRST	1	<b>MAC host interface soft reset</b> 0 Restore MAC, STAT, SAL, RX_WR, and TX_RD to normal operation. 1 Reset MAC, STAT, programmable registers in SAL, RX_WR, and TX_RD. Keep high for minimum of 5μsec to guarantee that all functions get reset.
D08	R/W	ITXA	0	<b>Insert transmit source address</b> 0 Source address for Ethernet transmit frame taken from data in TX_FIFO. 1 Insert the MAC Ethernet source address into the Ethernet transmit frame source address field. Set to force the MAC to automatically insert the Ethernet MAC source address into the Ethernet transmit frame source address. The SA1, SA2, and SA3 registers provide the address information. When the ITXA bit is cleared, the Ethernet MAC source address is taken from the data in the TX_FIFO.
D07	R/W	RXRAM	1	<b>RX FIFO RAM access</b> 0 CPU access to the RX FIFO RAM is disabled 1 CPU access to the RX FIFO RAM is enabled
D06:00	N/A	Reserved	N/A	N/A

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:08	R/W	Not used	0	Always write as 0.
D07	R/W	TCLER	0	<b>Clear transmit error</b> 0→1 transition: Clear transmit error. Clears out conditions in the transmit packet processor that have caused the processor to stop and require assistance from software before the processor can be restarted (for example, an AHB bus error or the TXBUFNR bit set in the Ethernet Interrupt Status register). Toggle this bit from low to high to restart the transmit packet processor.
D06:04	R/W	Not used	0	Always write as 0.
D03	R/W	TKICK	0	<b>Transmit DMA state machine enable</b> 0→1 transition, used by software to start a DMA transfer after a buffer descriptor has been updated.
D02	R/W	AUTOZ	0	<b>Enable statistics counter clear on read</b> 0 No change in counter value after read 1 Counter cleared after read When set, configures all counters in the Statistics module to clear on read. If AUTOZ is not set, the counters retain their value after a read. The counters can be cleared by writing all zeros.
D01	R/W	CLRCNT	1	<b>Clear statistics counters</b> 0 Do not clear all counters 1 Clear all counters When set, synchronously clears all counters in the Statistics module.
D00	R/W	STEN	0	<b>Enable statistics counters</b> 0 Counters disabled 1 Counters enabled When set, enables all counters in the Statistics module. If this bit is cleared, the counters will not update.

## Ethernet General Status register

Address: A060 0008

Bits	Access	Mnemonic	Reset	Description
D31:21	N/A	Reserved	N/A	N/A
D20	R/C	RXINIT	0x0	<b>RX initialization complete</b> Set when the RX_RD logic has completed the initialization of the local buffer descriptor registers requested when ERXINIT in Ethernet General Control Register #1 is set. The delay from ERXINIT set to RXINIT set is less than five microseconds.
D19:00	N/A	Reserved	N/A	N/A

## Ethernet Transmit Status register

Address: A060 0018

The Ethernet Status register contains the status for the last transmit frame. The TXDONE bit in the Ethernet Interrupt Status register (see page 317) is set upon completion of a transmit frame and the Ethernet Transmit Status register is loaded at the same time. Bits [15:0] are also loaded into the Status field of the last transmit buffer descriptor for the frame.

## Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TX OK	TX BR	TX MC	TX AL	TX AED	TX AEC	TX AUR	TX AJ	Not used	TX DEF	TX CRC	Not used	TXCOLC			

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:16	N/A	Reserved	N/A	N/A
D15	R	TXOK	0x0	<b>Frame transmitted OK</b> When set, indicates that the frame has been delivered to and emptied from the transmit FIFO without problems.
D14	R	TXBR	0x0	<b>Broadcast frame transmitted</b> When set, indicates the frame's destination address was a broadcast address.
D13	R	TXMC	0x0	<b>Multicast frame transmitted</b> When set, indicates the frame's destination address was a multicast address.
D12	R	TXAL	0x0	<b>TX abort — late collision</b> When set, indicates that the frame was aborted due to a collision that occurred beyond the collision window set in the Collision Window/Retry register. If this bit is set, the TX_WR logic stops processing frames and sets the TXERR bit in the Ethernet Interrupt Status register.
D11	R	TXAED	0x0	<b>TX abort — excessive deferral</b> When set, indicates that the frame was deferred in excess of 6071 nibble times in 100 Mbps or 24,287 times in 0 Mbps mode. This causes the frame to be aborted if the <i>excessive deferral bit</i> is set to 0 in MAC Configuration Register #2. If TXAED is set, the TX_WR logic stops processing frames and sets the TXERR bit in the Ethernet Interrupt Status register.
D10	R	TXAEC	0x0	<b>TX abort — excessive collisions</b> When set, indicates that the frame was aborted because the number of collisions exceeded the value set in the Collision Window/Retry register. If this bit is set, the TX_WR logic stops processing frames and sets the TXERR bit in the Ethernet Interrupt Status register.
D09	R	TXAUR	0x0	<b>TX abort — underrun</b> When set, indicates that the frame was aborted because the TX_FIFO had an underrun. If this bit is set, the TX_WR logic stops processing frames and sets the TXERR bit in the Ethernet Interrupt Status register.

Bits	Access	Mnemonic	Reset	Description
D08	R	TXAJ	0x0	<b>TX abort — jumbo</b> When set, indicates that the frame's length exceeded the value set in the Maximum Frame register. TXAJ is set only if the HUGE bit in MAC Configuration Register #2 is set to 0. Jumbo frames result in the TX buffer descriptor buffer length field being set to 0x000. If the HUGE bit is set to 0, the frame is truncated. If TXAJ is set, the TX_WR logic stops processing frames and sets the TXERR bit in the Ethernet Interrupt Status register.
D07	R	Not used	0x0	Always set to 0.
D06	R	TXDEF	0x0	<b>Transmit frame deferred</b> When set, indicates that the frame was deferred for at least one attempt, but less than the maximum number for an excessive deferral. TXDEF is also set when a frame was deferred due to a collision. This bit is not set for late collisions.
D05	R	TXCRC	0x0	<b>Transmit CRC error</b> When set, indicates that the attached CRC in the frame did not match the internally-generated CRC. This bit is not set if the MAC is inserting the CRC in the frame (that is, the CRCEN bit is set in MAC Configuration Register #2). If TXCRC is set, the TX_WR logic stops processing frames and sets the TXERR bit in the Ethernet Interrupt Status register.
D04	R	Not used	0x0	Always set to 0.
D03:00	R	TXCOLC	0x0	<b>Transmit collision count</b> Number of collisions the frame incurred during transmission attempts.

## Ethernet Receive Status register

Address: A060 001C

The Ethernet Receive Status register contains the status for the last completed receive frame. The RXBR bit in the Ethernet Interrupt Status register (see page 317) is set whenever a receive frame is completed and the Ethernet Receive Status register is loaded at the same time. Bits [15:0] are also loaded into the status field of the receive buffer descriptor used for the frame.

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:27	N/A	Reserved	N/A	N/A
D26:16	R	RXSIZE	0x000	<b>Receive frame size in bytes</b> Length of the received frame, in bytes.
D15	R	RXCE	0x0	<b>Receive carrier event previously seen</b> When set, indicates that a <i>carrier event</i> activity (an activity on the receive channel that does not result in a frame receive attempt being made) was found at some point since the last receive statistics. A carrier event results when the interface signals to the PHY have the following values: MRXER = 1 MRXDV = 0 RXD = 0xE The event is being reported with this frame, although it is not associated with the frame.
D14	R	RXDV	0x0	<b>Receive data violation event previously seen</b> Set when the last receive event was not long enough to be a valid frame.
D13	R	RXOK	0x0	<b>Receive frame OK</b> Set when the frame has a valid CRC and no symbol errors.
D12	R	RXBR	0x0	<b>Receive broadcast frame</b> Set when the frame has a valid broadcast address.
D11	R	RXMC	0x0	<b>Receive multicast frame</b> Set when the frame has a valid multicast address.
D10	N/A	Reserved	N/A	N/A
D09	R	RXDR	0x0	<b>Receive frame has dribble bits</b> Set when an additional 1–7 bits are received after the end of the frame.
D08:07	N/A	Reserved	N/A	N/A

Bits	Access	Mnemonic	Reset	Description
D06	R	RXSHT	0x0	<b>Receive frame is too short</b> Set when the frame's length is less than 64 bytes. Short frames are accepted only when the ERXSHT bit is set to 1 in Ethernet General Control Register #1.
D05:00	N/A	Reserved	N/A	N/A

## MAC Configuration Register #1

Address: A060 0400

MAC Configuration Register #1 provides bits that control functionality within the Ethernet MAC block.

### Register bit assignment

Bits	Access	Mnemonic	Reset	Definition
D31:15	N/A	Reserved	N/A	N/A
D14	R/W	EDEFER	0	<b>Excess deferral</b> 0 The MAC aborts when the excessive deferral limit is reached (that is, 6071 nibble times in 100 Mbps mode or 24,287 bit times in 10 Mbps mode). 1 Enables the MAC to defer to carrier indefinitely, as per the 802.3u standard.
D13	R/W	Not used	0	Always write to 0.
D12	R/W	NOBO	0	<b>No backoff</b> When this bit is set to 1, the MAC immediately retransmits following a collision, rather than using the binary exponential backoff algorithm (as specified in the 802.3u standard).
D11:10	N/A	Reserved	N/A	N/A

Bits	Access	Mnemonic	Reset	Definition
D09	R/W	LONGP	0	<b>Long preamble enforcement</b> 0 Allows any length preamble (as defined in the 802.3u standard). 1 The MAC allows only receive frames that contain preamble fields less than 12 bytes in length.
D08	R/W	PUREP	0	<b>Pure preamble enforcement</b> 0 No preamble checking is performed 1 The MAC certifies the content of the preamble to ensure that it contains 0x55 and is error-free.
D07	R/W	AUTOP	0	<b>Auto detect pad enable</b> When set to 1, this bit causes the MAC to detect automatically the type of transmit frame, either tagged or untagged, by comparing the two octets following the source address with the 0x8100 VLAN protect ID and pad accordingly. Note: This bit is ignored if PADEN is set to 0. See “PAD operation table for transmit frames” below.
D06	R/W	VLANP	0	<b>VLAN pad enable</b> Set to 1 to have the MAC pad all short transmit frames to 64 bytes and to append a valid CRC. This bit is used in conjunction with auto detect pad enable (AUTOP) and pad/CRC enable (PADEN). See “PAD operation table for transmit frames” below. This bit is ignored if PADEN is set to 0.
D05	R/W	PADEN	0	<b>Pad/CRC enable</b> 0 Short transmit frames not padded. 1 The MAC pads all short transmit frames. This bit is used in conjunction with auto detect pad enable (AUTOP) and VLAN pad enable (VLANP). See “PAD operation table for transmit frames” below.
D04	R/W	CRCEN	0	<b>CRC enable</b> 0 Transmit frames presented to the MAC contain a CRC. 1 Append a CRC to every transmit frame, whether padding is required or not. CRCEN must be set if PADEN is set to 1.
D03	R/W	Not used	0	Always write as 0.
D02	R/W	HUGE	0	<b>Huge frame enable</b> 0 Transmit and receive frames are limited to the MAXF value in the Maximum Frame register. 1 Frames of any length are transmitted and received.

Bits	Access	Mnemonic	Reset	Definition
D01	R/W	Not used	0	Always write as 0.
D00	R/W	FULLD	0	<b>Full-duplex</b> 0 The MAC operates in half-duplex mode. 1 The MAC operates in full-duplex mode.

### PAD operation table for transmit frames

Type	AUTOP	VLANP	PADEN	Action
Any	X	X	0	No pad; check CRC
Any	0	0	1	Pad to 60 bytes; append CRC
Any	X	1	1	Pad to 64 bytes; append CRC
Any	1	0	1	If untagged, pad to 60 bytes; append CRC If VLAN tagged, pad to 64 bytes; append CRC

## Register bit assignment

**Note:** If both SCAN and READ are set, SCAN takes precedence.

Bits	Access	Mnemonic	Reset	Description
D31:02	N/A	Reserved	N/A	N/A
D01	R/W	SCAN	0	<b>Automatically scan for read data</b> Set to 1 to have the MII Management module perform read cycles continuously. This is useful for monitoring link fail, for example. Note: SCAN must transition from a 0 to a 1 to initiate the continuous read cycles.
D00	R/W	READ	0	<b>Single scan for read data</b> Set to 1 to have the MII Management module perform a single read cycle. The read data is returned in the MII Management Read Data register after the BUSY bit in the MII Management Indicators register has returned to a value of 0. Note: READ must transition from a 0 to a 1 to initiate a single read cycle.

## MII Management Address register

Address: A060 0428

## Register

MWTD															

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:16	N/A	Reserved	N/A	N/A
D15:00	R/W	MWTD	0x0000	<b>MII write data</b> When this register is written, an MII Management write cycle is performed using this 16-bit data along with the preconfigured PHY device and PHY register addresses defined in the MII Management Address register. The write operation completes when the BUSY bit in the MII Management Indicators register returns to 0.

## MII Management Read Data register

Address: A060 0430

## Register

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:16	N/A	Reserved	N/A	N/A
D15:00	R	MRDD	0x0000	<b>MII read data</b> Read data is obtained by reading from this register after an MII Management read cycle. An MII Management read cycle is executed by loading the MII Management Address register, then setting the READ bit to 1 in the MII Management Command register. Read data is available after the BUSY bit in the MII Management Indicators register returns to 0.

## MII Management Indicators register

Address: A060 0434

## Register

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:04	N/A	Reserved	N/A	N/A
D03	R	MIILF	0	<b>MII link failure</b> When set to 1, indicates that the PHY currently has a link fail condition.

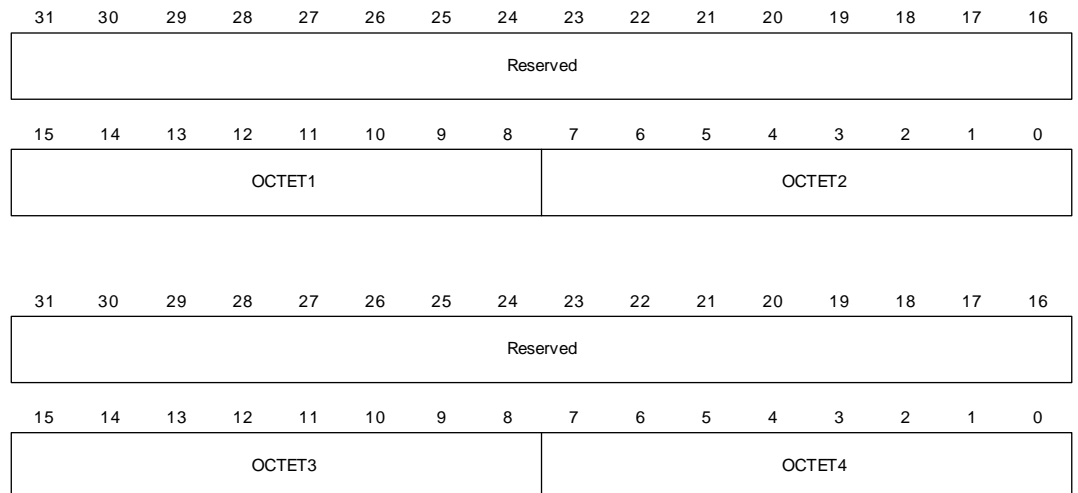

Bits	Access	Mnemonic	Reset	Description
D02	R	NVALID	0	<b>Read data not valid</b> When set to 1, indicates that the MII Management read cycle has not completed and the read data is not yet valid. Also indicates that SCAN READ is not valid for automatic scan reads.
D01	R	SCAN	0	<b>Automatically scan for read data in progress</b> When set to 1, indicates that continuous MII Management scanning read operations are in progress.
D00	R	BUSY	0	<b>MII interface BUSY with read/write operation</b> When set to 1, indicates that the MII Management module currently is performing an MII Management read or write cycle. This bit returns to 0 when the operation is complete.

## Station Address registers

Addresses: A060 0440 / 0444 / 0448

The 48-bit station address is loaded into Station Address Register #1, Station Address Register #2, and Station Address Register #3, for use by the station address logic (see “Station address logic (SAL)” on page 264).

### Registers

### Register bit assignments for all three registers

Bits	Access	Mnemonic	Reset	Description
<b>Station Address Register #1</b>				
D31:16	N/A	Reserved	N/A	N/A
D15:08	R/W	OCTET1	0	Station address octet #1 (stad[7:0])
D07:00	R/W	OCTET2	0	Station address octet #2 (stad[15:8])
<b>Station Address Register #2</b>				
D31:16	N/A	Reserved	N/A	N/A
D15:08	R/W	OCTET3	0	Station address octet #3 (stad[23:16])
D07:00	R/W	OCTET4	0	Station address octet #4 (stad[31:24])
<b>Station Address Register #3</b>				
D31:16	N/A	Reserved	N/A	N/A
D15:08	R/W	OCTET5	0	Station address octet #5 (stad[39:32])
D07:00	R/W	OCTET6	0	Station address octet #6 (stad[47:40])

**Note:** Octet #6 is the first byte of a frame received from the MAC. Octet #1 is the last byte of the station address received from the MAC.

## Station Address Filter register

Address: A060 0500

The Station Address Filter register contains several filter controls. The register is located in the station address logic (see “Station address logic (SAL)” on page 264).

All filtering conditions are independent of each other. For example, the station address logic can be programmed to accept all multicast frames, all broadcast frames, and frames to the programmed destination address.

**Register****Register bit assignment**

Bits	Access	Mnemonic	Reset	Description
D31:04	N/A	Reserved	N/A	N/A
D03	R/W	PRO	0	Enable promiscuous mode; receive all frames
D02	R/W	PRM	0	Accept all multicast frames
D01	R/W	PRA	0	Accept multicast frames using the hash table
D00	R/W	BROAD	0	Accept all broadcast frames

**RegisterHash Tables**

The MAC receiver provides the station address logic with a 6-bit CRC value that is the upper six bits of a 32-bit CRC calculation performed on the 48-bit multicast destination address. This 6-bit value addresses the 64-bit multicast hash table created in HT1 (hash table 1) and HT2 (hash table 2). If the current receive frame is a multicast frame and the 6-bit CRC addresses a bit in the hash table that is set to 1, the receive frame will be accepted; otherwise, the receive frame is rejected.

HT1 stores enables for the lower 32 CRC addresses; HT2 stores enables for the upper 32 CRC addresses.

**HT1**

Address: A060 0504

**Register bit assignment**

Bits	Access	Mnemonic	Reset	Description
D31:00	R/W	HT1	0x00000000	CRC 31:00

## HT2

Address: A060 0508

### Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:00	R/W	HT2	0x00000000	CRC 63:32

## Statistics registers

Address: A060 0680 (base register)

The Statistics module has 39 counters and 4 support registers that count and save Ethernet statistics. The Ethernet General Control Register #2 contains three Statistics module configuration bits: AUTOZ, CLRCNT, and STEN. The counters support a “clear on read” capability that is enabled when AUTOZ is set to 1.

### Combined transmit and receive statistics counters address map

The combined transmit and receive statistics counters are incremented for each good or bad frame, transmitted and received, that falls within the specified frame length limits of the counter (for example, TR127 counts 65-127 byte frames). The frame length excludes framing bits and includes the FCS (checksum) bytes. All counters are 18 bits, with this bit configuration:

D31:18	R	Reserved
D17:00	R/W	Reset = 0x00000 Count (R/W)

Address	Register	Transmit and receive counters			R/W
A060_0680	TR64	Transmit & receive 64		Byte frame counter	R/W
A060_0684	TR127	Transmit & receive 65	to	127 Byte frame counter	R/W
A060_0688	TR255	Transmit & receive 128	to	255 Byte frame counter	R/W
A060_068C	TR511	Transmit & receive 256	to	511 Byte frame counter	R/W
A060_0690	TR1K	Transmit & receive 512	to	1023 Byte frame counter	R/W

Address	Register	Transmit and receive counters			R/W
A060_0694	TRMAX	Transmit & receive 1024	to	1518 Byte frame counter	R/W
A060_0698	TRMGV	Transmit & receive 1519	to	1522 Byte good VLAN frame count	R/W

### Receive statistics counters address map

Address	Register	Receive counters	R/W
A060_069C	RBYT	Receive byte counter	R/W
A060_06A0	RPKT	Receive packet counter	R/W
A060_06A4	RFCS	Receive FCS error counter	R/W
A060_06A8	RMCA	Receive multicast packet counter	R/W
A060_06AC	RBCA	Receive broadcast packet counter	R/W
A060_06B0	RXCF	Receive control frame packet counter	R/W
A060_06B4	RXPF	Receive PAUSE frame packet counter	R/W
A060_06B8	RXUO	Receive unknown OP CODE counter	R/W
A060_06BC	RALN	Receive alignment error counter	R/W
A060_06C0	Reserved	N/A	N/A
A060_06C4	RCDE	Receive code error counter	R/W
A060_06C8	RCSE	Receive carrier sense error counter	R/W
A060_06CC	RUND	Receive undersize packet counter	R/W
A060_06D0	ROVR	Receive oversize packet counter	R/W
A060_06D4	RFRG	Receive fragments counter	R/W
A060_06D8	RJBR	Receive jabber counter	R/W
A060_06DC	Reserved	N/A	N/A

### Receive byte counter (A060 069C)

Incremented by the byte count of frames received with 0 to 1518 bytes, including those in bad packets, excluding framing bits but including FCS bytes.

D31:24	R	Reset = Read as 0	Reserved
D23:00	R/W	Reset = 0x000000	RBYT

### Receive packet counter (A060 06A0)

Incremented for each received frame (including bad packets, and all unicast, broadcast, and multicast packets).

D31:18	R	Reset = Read as 0	Reserved
--------	---	-------------------	----------

D17:00 R/W Reset = 0x00000 RPKT

**Receive FCS error counter (A060 06A4)**

Incremented for each frame received with a length of 64 to 1518 bytes, and containing a frame check sequence (FCS) error. FCS errors are not counted for VLAN frames that exceed 1518 bytes or for any frames with dribble bits.

D31:12 R Reset = Read as 0 Reserved

D11:00 R/W Reset = 0x000 RFCS

**Receive multicast packet counter (A060 06A8)**

Incremented for each good multicast frame with a length no greater than 1518 bytes (non-VLAN) or 1522 bytes (VLAN), excluding broadcast frames. This counter does not look at range/length errors.

D31:18 R Reset = Read as 0 Reserved

D17:00 R/W Reset = 0x00000 RMCA

**Receive broadcast packet counter (A060 06AC)**

Incremented for each good broadcast frame with a length no greater than 1518 bytes (non-VLAN) or 1522 bytes (VLAN), excluding multicast frames. This counter does not look at range/length errors.

D31:18 R Reset = Read as 0 Reserved

D17:00 R/W Reset = 0x00000 RBCA

**Receive control frame packet counter (A060 06B0)**

Incremented for each MAC control frame received (PAUSE and unsupported).

D31:12 R Reset = Read as 0 Reserved

D11:00 R/W Reset = 0x000 RXCF

**Receive PAUSE frame packet counter (A060 06B4)**

Incremented each time a valid PAUSE control frame is received.

D31:12 R Reset = Read as 0 Reserved

D11:00 R/W Reset = 0x000 RXPf

**Receive unknown OP CODE packet counter (A060 06B8)**

Incremented each time a MAC control frame is received with an OP CODE other than PAUSE.

D31:12 R Reset = Read as 0 Reserved

D11:00 R/W Reset = 0x000 RBUO

**Receive alignment  
error counter  
(A060 06BC)**

Incremented for each received frame, from 64 to 1518 bytes, that contains an invalid FCS and has dribble bits (that is, is not an integral number of bytes).

D31:12	R	Reset = Read as 0	Reserved
D11:00	R/W	Reset = 0x000	RALN

**Receive code  
error counter  
(A060 06C4)**

Incremented each time a valid carrier was present and at least one invalid data symbol was found.

D31:12	R	Reset = Read as 0	Reserved
D11:00	R/W	Reset = 0x000	RCDE

**Receive carrier  
sense error  
counter (A060  
06C8)**

Incremented each time a false carrier is found during idle, as defined by a 1 on RX\_ER and an 0xE on RXD. The event is reported with the statistics generated on the next received frame. Only one false carrier condition can be detected and logged between frames.

D31:12	R	Reset = Read as 0	Reserved
D11:00	R/W	Reset = 0x000	RCSE

**Receive undersize  
packet counter  
(A060 06CC)**

Incremented each time a frame is received that is less than 64 bytes in length, contains a valid FCS, and is otherwise well-formed. This counter does not look at range/length errors.

D31:12	R	Reset = Read as 0	Reserved
D11:00	R/W	Reset = 0x000	RUND

**Receive oversize  
packet counter  
(A060 06D0)**

Incremented each time a frame is received that exceeds 1518 bytes (non-VLAN) or 1522 bytes (VLAN), contains a valid FCS, and is otherwise well-formed. This counter does not look at range/length errors. This counter is not incremented when a packet is truncated because it exceeds the MAXF value.

D31:12	R	Reset = Read as 0	Reserved
D11:00	R/W	Reset = 0x000	ROVR

**Receive fragments  
counter (A060  
06D4)**

Incremented for each frame received that is less than 64 bytes in length and contains an invalid FCS; this includes integral and non-integral lengths.

D31:12	R		Reserved
D11:00	R/W	Reset = 0x000	RFRG

**Receive jabber counter (A060 06D8)**

Incremented for frames received that exceed 1518 bytes (non-VLAN) or 1522 bytes (VLAN) and contain an invalid FCS, including alignment errors. This counter does not increment when a packet is truncated to 1518 (non-VLAN) or 1522 (VLAN) bytes by MAXF.

D31:12	R	Reset = Read as 0	Reserved
D11:00	R/W	Reset = 0x000	RJBR

**Transmit statistics counters address map**

Address	Register	Transmit counters	R/W
A060_06E0	TBYT	Transmit byte counter	R/W
A060_06E4	TPKT	Transmit packet counter	R/W
A060_06E8	TMCA	Transmit multicast packet counter	R/W
A060_06EC	TBCA	Transmit broadcast packet counter	R/W
A060_06F0	Reserved	N/A	N/A
A060_06F4	TDFR	Transmit deferral packet counter	R/W
A060_06F8	TEDF	Transmit excessive deferral packet counter	R/W
A060_06FC	TSCL	Transmit single collision packet counter	R/W
A060_0700	TMCL	Transmit multiple collision packet counter	R/W
A060_0704	TLCL	Transmit late collision packet counter	R/W
A060_0708	TXCL	Transmit excessive collision packet counter	R/W
A060_070C	TNCL	Transmit total collision counter	R/W
A060_0710	Reserved	N/A	N/A
A060_0714	Reserved	N/A	N/A
A060_0718	TJBR	Transmit jabber frame counter	R/W
A060_071C	TFCS	Transmit FCS error counter	R/W
A060_0720	Reserved	N/A	N/A
A060_0724	TOVR	Transmit oversize frame counter	R/W
A060_0728	TUND	Transmit undersize frame counter	R/W
A060_072C	TFRG	Transmit fragments frame counter	R/W

**Transmit byte counter (A060 06E0)**

Incremented by the number of bytes that were put on the wire, including fragments of frames that were involved with collisions. This count does not include preamble/SFD or jam bytes.

D31:24	R	Reset = Read as 0	Reserved
D23:00	R/W	Reset = 0x000000	TBYT

**Transmit packet counter (A060 06E4)**

Incremented for each transmitted packet (including bad packets, excessive deferred packets, excessive collision packets, late collision packets, and all unicast, broadcast, and multicast packets).

D31:18	R	Reset = Read as 0	Reserved
D17:00	R/W	Reset = 0x00000	TPKT

**Transmit multicast packet counter (A060 06E8)**

Incremented for each multicast valid frame transmitted (excluding broadcast frames).

D31:18	R	Reset = Read as 0	Reserved
D17:00	R/W	Reset = 0x00000	TMCA

**Transmit broadcast packet counter (A060 06EC)**

Incremented for each broadcast frame transmitted (excluding multicast frames).

D31:18	R	Reset = Read as 0	Reserved
D17:00	R/W	Reset = 0x00000	TBCA

**Transmit deferral packet counter (A060 06F4)**

Incremented for each frame that was deferred on its first transmission attempt. This counter does not include frames involved in collisions.

D31:12	R	Reset = Read as 0	Reserved
D11:00	R/W	Reset = 0x000	TDFR

**Transmit excessive deferral packet counter (A060 06F8)**

Incremented for frames aborted because they were deferred for an excessive period of time (3036 byte times).

D31:12	R	Reset = Read as 0	Reserved
D11:00	R/W	Reset = 0x000	TEDF

**Transmit single collision packet counter (A060 06FC)**

Incremented for each frame transmitted that experienced exactly one collision during transmission.

D31:12	R	Reset = Read as 0	Reserved
D11:00	R/W	Reset = 0x000	TSCL

**Transmit multiple collision packet counter (A060 0700)**

Incremented for each frame transmitted that experienced 2-15 collisions (including any late collisions) during transmission.

D31:12	R	Reset = Read as 0	Reserved
D11:00	R/W	Reset = 0x000	TMCL

**Transmit late collision packet counter (A060 0704)**

Incremented for each frame transmitted that experienced a late collision during a transmission attempt. Late collisions are defined using the CWIN[13:08] field of the Collision Window/Retry register.

D31:12	R	Reset = Read as 0	Reserved
D11:00	R/W	Reset = 0x000	TLCL

**Transmit excessive collision packet counter (A060 0708)**

Incremented for each frame transmitted that experienced excessive collisions during transmission, as defined by the RETX [03:00] field of the Collision Window/Retry register, and was aborted.

D31:12	R	Reset = Read as 0	Reserved
D11:00	R/W	Reset = 0x000	TXCL

**Transmit total collision packet counter (A060 070C)**

Incremented by the number of collisions experienced during the transmission of a frame.

**Note:** This register does not include collisions that result in an excessive collision count or late collisions.

D31:12	R	Reset = Read as 0	Reserved
D11:00	R/W	Reset = 0x000	TNCL

**Transmit jabber frame counter (A060 0718)**

Incremented for each oversized transmitted frame with an incorrect FCS value.

D31:12	R	Reset = Read as 0	Reserved
D11:00	R/W	Reset = 0x000	TJBR

**Transmit FCS error counter (A060 071C)**

Incremented for every valid-sized packet with an incorrect FCS value.

D31:12	R	Reset = Read as 0	Reserved
D11:00	R/W	Reset = 0x000	TFCS

**Transmit oversize frame counter (A060 0724)**

Incremented for each transmitted frame that exceeds 1518 bytes (NON\_VLAN) or 1532 bytes (VLAN) and contains a valid FCS.

D31:12	R	Reset = Read as 0	Reserved
D11:00	R/W	Reset = 0x000	TOVR

**Transmit undersize frame counter (A060 0728)**

Incremented for every frame less than 64 bytes, with a correct FCS value. This counter also is incremented when a jumbo packet is aborted and the MAC is not checking the FCS, because the frame is reported as having a length of 0 bytes.

D31:12	R	Reset = Read as 0	Reserved
D11:00	R/W	Reset = 0x000	TUND

**Transmit fragment counter (A060 072C)**

Incremented for every frame less than 64 bytes, with an incorrect FCS value.

D31:12	R	Reset = Read as 0	Reserved
D11:00	R/W	Reset = 0x000	TFRG

**General Statistics registers address map**

These are the General Statistics registers.

Address	Register	General registers	R/W
A060_0730	CAR1	Carry Register 1	R
A060_0734	CAR2	Carry Register 2	R
A060_0738	CAM1	Carry Register 1 Mask register	R/W
A060_073C	CAM2	Carry Register 2 Mask register	R/W

Carry Register 1 (CAR1) and Carry Register 2 (CAR2) have carry bits for all of the statistics counters. These carry bits are set when the associated counter reaches a rollover condition.

These carry bits also can cause the STOVFL (statistics counter overflow) bit in the Ethernet Interrupt Status register to be set. Carry Register 1 Mask register (CAM1) and Carry Register 2 Mask register (CAM2) have individual mask bits for each of the carry bits. When set, the mask bit prevents the associated carry bit from setting the STOVFL bit.

**Carry Register 1**

Address: A060 0730

## RX\_A Buffer Descriptor Pointer register

Address: A060 0A00

### Register

### Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:00	R/W	RXAPTR	0x00000000	<b>RX_A Buffer Descriptor Pointer</b> Contains a pointer to the initial receive buffer descriptor for the A pool of buffers.

## RX\_B Buffer Descriptor Pointer register

Address: A060 0A04

### Register

### Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:00	R/W	RXBPTR	0x00000000	<b>RX_B Buffer Descriptor Pointer</b> Contains a pointer to the initial receive buffer descriptor for the B pool of buffers.

## RX\_C Buffer Descriptor Pointer register

Address: A060 0A08

### Register

### Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:00	R/W	RXCPTTR	0x00000000	<b>RX_C Buffer Descriptor Pointer</b> Contains a pointer to the initial receive buffer descriptor for the C pool of buffers.

## RX\_D Buffer Descriptor Pointer register

Address: A060 0A0C

### Register

### Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:00	R/W	RXDPTR	0x00000000	<b>RX_D Buffer Descriptor Pointer</b> Contains a pointer to the initial receive buffer descriptor for the D pool of buffers.

## Ethernet Interrupt Status register

Address: A060 0A10

The Ethernet Interrupt Status register contains status bits for all of the Ethernet interrupt sources. Each interrupt status bit is assigned to either the RX or TX Ethernet interrupt; bits D25:16 are assigned to the RX interrupt and D06:00 are assigned to the TX interrupt.

The bits are set to indicate an interrupt condition, and are cleared by writing a 1 to the appropriate bit. All interrupts bits are enabled using the Ethernet Interrupt Enable register (EINTREN). If any enabled bit in the Ethernet Interrupt Status register is set, its associated Ethernet interrupt to the system is set. The interrupt to the system is negated when all active interrupt sources have been cleared. If an interrupt source is active at the same time the interrupt bit is being cleared, the interrupt status bit remains set and the interrupt signal remains set.

**Note:** For diagnostics, software can cause any of these interrupt status bits to be set by writing a 1 to a bit that is 0.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:26	N/A	Reserved	N/A	N/A
D25	R/C	RXOVFL_DATA	0	Assigned to RX interrupt. RX data FIFO overflowed. For proper operation, reset the receive packet processor using the ERX bit in the Ethernet General Control Register #1 when an overflow condition occurs.
D24	R/C	RXOVFL_STAT	0	Assigned to RX interrupt. RX status FIFO overflowed.
D23	R/C	RXBUFC	0	Assigned to RX interrupt. I bit set in receive Buffer Descriptor and buffer closed.
D22	R/C	RXDONEA	0	Assigned to RX interrupt. Complete receive frame stored in pool A of system memory.

Bits	Access	Mnemonic	Reset	Description
D21	R/C	RXDONEB	0	Assigned to RX interrupt. Complete receive frame stored in pool B of system memory.
D20	R/C	RXDONEC	0	Assigned to RX interrupt. Complete receive frame stored in pool C of system memory.
D19	R/C	RXDONED	0	Assigned to RX interrupt. Complete receive frame stored in pool D of system memory.
D18	R/C	RXNOBUF	0	Assigned to RX interrupt. No buffer is available for this frame due to one of these conditions: <ul style="list-style-type: none"> <li>■ All four buffer rings being disabled</li> <li>■ All four buffer rings being full</li> <li>■ No available buffer big enough for the frame</li> </ul>
D17	R/C	RXBUFFUL	0	Assigned to RX interrupt. No buffer is available for this frame because all four buffer rings are disabled or full.
D16	R/C	RXBR	0	Assigned to RX interrupt. New frame available in the RX_FIFO. This bit is used for diagnostics.
D15:07	N/A	Reserved	N/A	N/A
D06	R/C	STOVFL	0	Assigned to TX interrupt. Statistics counter overflow. Individual counters can be masked using the Carry Register 1 and 2 Mask registers. The source of this interrupt is cleared by clearing the counter that overflowed, and by clearing the associated carry bit in either Carry Register 1 or Carry Register 2 by writing a 1 to the bit.
D05	R	Not used	0	Always write as 0.
D04	R/C	TXBUFC	0	Assigned to TX interrupt. I bit set in the Transmit Buffer Descriptor and buffer closed.
D03	R/C	TXBUFNR	0	Assigned to TX interrupt. F bit not set in the Transmit Buffer Descriptor when read from the TX Buffer descriptor RAM.
D02	R/C	TXDONE	0	Assigned to TX interrupt. Frame transmission complete.

Bits	Access	Mnemonic	Reset	Description
D01	R/C	TXERR	0	Last frame not transmitted successfully. Assigned to TX interrupt. See “Ethernet Interrupt Status register” on page 317 for information about restarting the transmitter when this bit is set.
D00	R/C	TXIDLE	0	TX_WR logic has no frame to transmit. Assigned to TX interrupt. See “Ethernet Interrupt Status register” on page 317 for information about restarting the transmitter when this bit is set.

## Ethernet Interrupt Enable register

Address: A060 0A14

The Ethernet Interrupt Enable register contains individual enable bits for each of the bits in the Ethernet Interrupt Status register. When these bits are cleared, the corresponding bit in the Ethernet Interrupt Status register cannot cause the interrupt signal to the system to be asserted when it is set.

D09:00	R	TXOFF	0x000	Contains a 10-bit byte offset from the start of the transmit ring in the TX buffer descriptor RAM. The offset is updated at the end of the TX packet, and will have the offset to the next buffer descriptor that will be used. TXOFF can be used to determine from where the TX_WR logic will grab the next packet.

**RX Free Buffer register**

Address: A060 0A3C

So the RX\_RD logic knows when the software is freeing a buffer for reuse, the software writes to the RXFREE register each time it frees a buffer in one of the pools. RXFREE has an individual bit for each pool; this bit is set to 1 when the register is written. Reads to RXFREE always return all 0s.

## Multicast Address Filter registers

Each of the eight entries in the multicast address filter logic has individual registers to hold its 48-bit multicast address. The multicast address for each entry is split between two registers. Each entry has a register that contains the lower 32 bits of the multicast address and a separate register that contains the upper 16 bits of the address. For an explanation of the synchronization scheme used for these registers, see "Clock synchronization" on page 276.

D15:00	R/W	Default = 0x0000 0000	MFILTH7

**Multicast Address Mask registers**

Each of the eight entries in the multicast address filter logic has individual mask registers that extend the filtering range of each entry. The multicast address mask for each entry is split between two registers. Each entry has a register that contains the lower 32 bits of the multicast mask and a separate register that contains the upper 16 bits of the mask.

- Bits are set to 1 in the mask to enable or include that bit in the address filter.
- Bits are set to 0 in the mask if they are not included or are disabled in the address filter. These bits become *don't cares*.

For an explanation of the synchronization scheme used for these registers, see "Clock synchronization" on page 276.

## TX Buffer Descriptor RAM

Address: A060 1000

The TX buffer descriptor RAM holds 64 transmit buffer descriptors on-chip. Each buffer descriptor occupies four locations in the RAM, and the RAM is implemented as a 256x32 device. This is the format of the TX buffer descriptor RAM:

## Offset+0

D31:00 R/W Source address

### Offset+4

D31:11	R/W	Not used
D10:00	R/W	Buffer length

### Offset+8

D31:00	R/W	Destination address (not used)
--------	-----	--------------------------------

### Offset+C

D31	R/W	W	Wrap
D30	R/W	I	Interrupt on buffer completion
D29	R/W	L	Last buffer on transmit frame
D28	R/W	F	Buffer full
D27:16	R/W	Reserved	N/A
D15:00	R/W	Status	Transmit status from MAC

See “Transmit buffer descriptor format” on page 270, for more information about the fields in Offset+C.

## RX FIFO RAM

Address: A060 2000 (512 locations)

The 2k Byte RX FIFO RAM can be used by the CPU as a scratch pad memory during boot up. CPU access is enabled by setting the RXRAM bit in the Ethernet General Control Register 1. This bit must be cleared before enabling the Ethernet receiver.

### Register

### Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:00	R/W	Scr Mem	0	CPU scratch pad memory

## Sample hash table code

This sample C code describes how to calculate hash table entries based on 6-byte Ethernet destination addresses and a hash table consisting of two 32-bit registers (HT1 and HT2). HT1 contains locations 31:0 of the hash table; HT2 contains locations 63:32 of the hash table.

The pointer to the hash table is bits [28:23] of the Ethernet destination address CRC. The polynomial is the same as that used for the Ethernet FCS:

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

```
static ETH_ADDRESS mca_address[MAX_MCA];      /*list of MCA addresses*/
static INT16 mca_count;                       /*# of MCA addresses*/
```

```
/  *
  *
  * Function: void eth_load_mca_table (void)
  *
  * Description:
  *
  * This routine loads the MCA table. It generates a hash table for
  * the MCA addresses currently registered and then loads this table
  * into the registers HT1 and HT2.
  *
  * Parameters:
  *
  *     none
  *
  * Return Values:
  *
  *     none
  *
  */
```

```
static void eth_load_mca_table (void)

{
    WORD32 has_table[2];

    // create hash table for MAC address
    eth_make_hash_table (has_table);
```

```

        (*MERCURY_EFE).ht2.bits.data = SWAP32(hash_table[1]);
        (*MERCURY_EFE).ht1.bits.data = SWAP32(hash_table[0]);
    }

/  *
  *
  * Function: void eth_make_hash_table (WORD32 *hash_table)
  *
  * Description:
  *
  *     This routine creates a hash table based on the CRC values of
  *     the MAC addresses setup by set_hash_bit(). The CRC value of
  *     each MAC address is calculated and the lower six bits are used
  *     to generate a value between 0 and 64. The corresponding bit in
  *     the 64-bit hash table is then set.
  *
  * Parameters:
  *
  *     hash_table           pointer to buffer to store hash table in.
  *
  * Return Values:
  *
  *     none
  *
  */

```

# External DMA

## C H A P T E R 7

The external DMA interface provides two external channels for external peripheral support. Each DMA channel moves data from the source address to the destination address. These addresses can specify any peripheral on the AHB bus but, ideally, they specify an external peripheral and external memory.

### DMA transfers

DMA transfers can be specified as burst-oriented to maximize AHB bus efficiency. All transfers are performed in two steps:

- 1 Data is moved from the source address to a 32-byte buffer in the DMA control logic.
- 2 The data is moved from the 32-byte buffer to the destination address.

These two steps are repeated until the DMA transfer is complete.

**Note:** Optimal performance is achieved when both the source address and destination address are aligned.

#### Initiating DMA transfers

DMA transfers can be initiated in one of two ways: processor-initiated and external peripheral initiated.

#### Processor-initiated

The processor must do these steps in the order shown:

- 1 Set up the required buffer descriptors.
- 2 Configure the DMA Control register for each channel.
- 3 Write a 1 to both the CE field and the CG field in the DMA Control register for each channel.

#### External peripheral-initiated

An external peripheral initiates a DMA transfer by asserting the appropriate REQ signal. Software must have set up the required buffer descriptors as well as the DMA Control register for each channel, including setting the CE field to 1, before the REQ signal can be asserted.

# DMA buffer descriptor

All DMA channels use a buffer descriptor. When a DMA channel is activated, it reads the DMA buffer descriptor that the Buffer Descriptor Pointer register points to. A DMA buffer descriptor is always fetched using an AHB INCR4 transaction to maximize AHB bus bandwidth. When the current descriptor is retired, the next descriptor is accessed from a circular buffer.

Each DMA buffer requires four 32-bit words to describe a transfer. Multiple buffer descriptors are located in circular buffers of 4096 bytes. The DMA channel’s buffer descriptor pointer provides the first buffer descriptor address. Subsequent buffer descriptors are found adjacent to the first descriptor. The final buffer descriptor is defined with its W bit set. When the DMA channel finds the W bit, the channel wraps around to the first descriptor.

Each DMA channel can address a maximum of 256 buffer descriptors.

**Important:** A DMA channel configured for more than the maximum number of buffer descriptors operates in an unpredictable fashion.

## DMA buffer descriptor diagram

	31	30	29	28		16	15		0
OFFSET + 0	Source address								
OFFSET + 4	Reserved						Buffer length		
OFFSET + 8	Destination address								
OFFSET + C	W	I	L	F	Reserved			Status	

Field descriptions follow.

## Source address [pointer]

The source address pointer field identifies the starting location of the source data. The source address can be aligned to any byte boundary.

**Note:** Optimal performance is achieved when the source address is aligned on a word boundary.

## Buffer length

Buffer length indicates the number of bytes to move between the source and the destination. After completing the transfer, the DMA controller updates this field with the actual number of bytes moved. This is useful for debugging error conditions or determining the number of bytes transferred before the DONE signal was asserted.

## Destination address [pointer]

The description address pointer field identifies the starting location of the source data’s destination; that is, to where the source data needs to be moved. The destination address can be aligned to any byte boundary.

**Note:** Optimal performance is achieved when the destination address is aligned on a word boundary.

#### Status

This field is not used. Read back 0x0000.

#### Wrap (W) bit

The Wrap (W) bit, when set, tells the DMA controller that this is the last buffer descriptor within the continuous list of descriptors. The next buffer descriptor is found using the initial DMA channel buffer descriptor pointer. When the W bit is not set, the next buffer descriptor is found using an offset of 0x10 from the current buffer descriptor.

#### Interrupt (I) bit

The Interrupt (I) bit, when set, tells the DMA controller to issue an interrupt to the CPU when the buffer is closed due to a normal channel completion. The interruption occurs regardless of the normal completion interrupt enable configuration for the DMA channel.

#### Last (L) bit

The Last (L) bit, when set, tells the DMA controller that this buffer descriptor is the last descriptor that completes an entire message frame. The DMA controller uses this bit to assert the normal channel completion status when the byte count reaches zero.

#### Full (F) bit

The Full (F) bit, when set, indicates that the buffer descriptor is valid and can be processed by the DMA channel. The DMA channel clears this bit after completing the transfer(s).

The DMA channel does not try a transfer with the F bit clear. The DMA channel enters an idle state upon fetching a buffer descriptor with the F bit cleared. Whenever the F bit is modified by the device driver, the device driver must also write a 1 to the CE bit in the DMA Control register to activate the idle channel.

## Descriptor list processing

Once a DMA controller has completed the operation specified by the current buffer descriptor, it clears the F bit and fetches the next buffer descriptor. A DMA channel asserts the NRIP field (buffer not ready interrupt pending) in the DMA Status register and returns to the idle state upon fetching a buffer descriptor with the F bit in the incorrect state. A DMA channel always closes the current descriptor and moves on to the next descriptor when a DMA transfer is terminated by the assertion of the DONE signal.

## Peripheral DMA read access

The diagrams in this section describe how the DMA engine performs read accesses of an external peripheral.

- The CLK signal shown is for reference, and its frequency is equal to the speed grade of the part.
- The peripheral data enable signal (PDEN) is an AND function of the active states of the `st_cs_n[n]` and `st_oe_n` signals.
- PDEN timing can be adjusted by the memory controller's Static Memory Configuration 0-3 registers, which control `st_cs_n[n]` and `st_oe_n`.

**Note:** The PDEN signal is asserted for all accesses on the selected peripheral chip select. If configuration registers or memory also need to be accessed, you can use high level address bits and an external gate to disable the PDEN signal. You can also place the peripheral and configuration registers on separate chip selects to avoid the need for the external gate.

### Determining the width of PDEN

DMA read accesses from an external peripheral are treated as asynchronous operations by the chip. It is critical that the necessary width of the PDEN assertion be computed correctly and programmed in the static memory controllers.

Use this equation to compute total access time:

$$\text{Total access time} = T_a + T_b + T_c + 10.0$$

### Equation variables

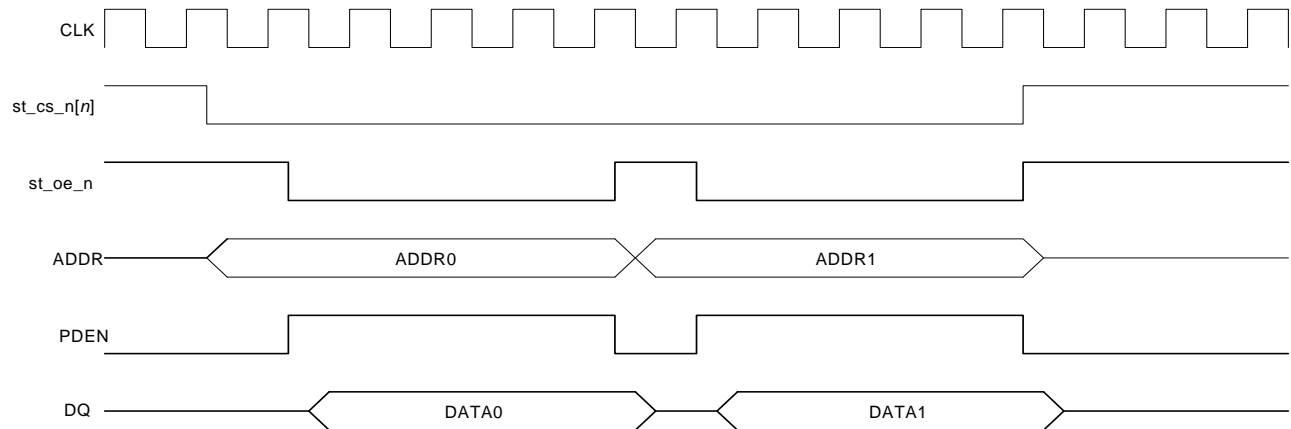

Variable	Definition
$T_a$	Peripheral read access time
$T_b$	Total board propagation delay including buffers
$T_c$	One AHB CLK cycle period

## Peripheral DMA single read access

## Peripheral DMA burst read access

## Peripheral DMA write access

The diagrams in this section describe how the DMA engine performs write accesses of an external peripheral. The CLK signal shown is for reference, and its frequency is equal to the speed grade of the part. For peripheral writes, the PDEN signal is an AND function of the active status of `st_cs_n[n]` and `we_n`. Write data into the peripheral on the falling edge of the PDEN signal. Data and control signals are always held after the falling edge of PDEN for one reference CLK cycle.

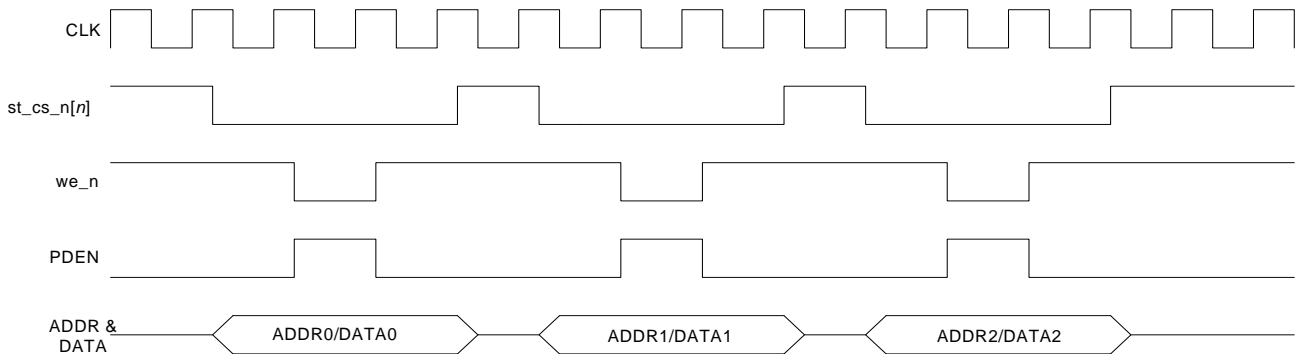

## Determining the width of PDEN

Use the memory controller's Static Memory Write Delay register and Static Memory Write Enable Delay register to determine the width of the PDEN assertion.

## Peripheral DMA single write access

## Peripheral DMA burst write access

## Peripheral REQ and DONE signaling

The processor treats the REQ and DONE signals as asynchronous, level signals.

### REQ signal

- The external peripheral can initiate a DMA transfer at any time by asserting the REQ signal.
- The external peripheral can pause the DMA transfer at any time by deasserting the REQ signal.
- The REQ signal can be deasserted during a transfer but if the peripheral is configured for burst access, the burst completes. The DMA transfer control logic remains paused until the REQ signal is reasserted.

## DONE signal

- The external peripheral can terminate the DMA transfer at any time by asserting the DONE signal. The peripheral must also deassert the REQ signal when it asserts the DONE signal.
- The DONE signal can be asserted during a transfer but if the peripheral is configured for burst access, the burst completes. When the DMA control logic finds a DONE assertion, it closes the current buffer descriptor, asserts a premature buffer completion status, and pauses until the REQ signal is reasserted. The DONE cycle must be deasserted no later than four AHB clock cycles before reasserting the REQ signal.

## Special circumstances

- For memory-to-memory DMA transfers that are initiated by software writing a 1 to the channel go (CG) field in the DMA Control register, the DMA control logic ignores the REQ and DONE signals.
- For memory-to-peripheral transfers, the DMA control logic ignores the DONE signal.

## Static RAM chip select configuration

The AHB DMA controller accesses an external peripheral using the external memory bus and one of the static ram chip select signals (`st_cs_n[N]`).

## Static ram chip select configuration

This table shows how to program the static ram chip select control registers for access using the AHB DMA controller. Fields not explicitly listed must be left in the reset state. Fields listed but not defined must be defined by you.

Register name	Field	Value	Comment
Configuration	PB	1	System requirement
	PM	User-defined	Set to 1 if it is not necessary for the chip select signal to toggle for each access.
	MW	User-defined	
Read Delay	WTRD	User-defined	To determine the read delay:
			1 Use this equation to compute the total delay:
			$T_a + T_b + T_c + 10.0$
			8 Divide the total delay by the AHB clock period
Page Read Delay	WTPG	user-defined	9 Round up any fractional value
			For most applications, this is the same value as the WTRD value.

Register name	Field	Value	Comment
Output Enable Delay	WOEN	User-defined	For most applications, this field can be set to 0.
Write Enable Delay	WWEN	User-defined	For most applications, this field can be left in the default state.
Write Delay	WTWR	User-defined	For most applications, this field can be left in the default state.
Turn Delay	WTTN	User-defined	For most applications, this field can be left in the default state.

## Control and Status registers

The external DMA configuration registers are located at base address 0xA080\_0000. All the configuration registers are accessed with zero wait states.

### Register address map

These are the external DMA control and status registers.

Address	Description	Access	Reset value
0xA080_0000	DMA Channel 1 Buffer Descriptor Pointer	R/W	0x00000000
0xA080_0004	DMA Channel 1 Control register	R/W	0x00000000
0xA080_0008	DMA Channel 1 Status and Interrupt Enable	R/W	0x00000000
0xA080_000C	DMA Channel 1 Peripheral Chip Select	R/W	0x00000000
0xA080_0010	DMA Channel 2 Buffer Descriptor Pointer	R/W	0x00000000
0xA080_0014	DMA Channel 2 Control register	R/W	0x00000000
0xA080_0018	DMA Channel 2 Status and Interrupt Enable	R/W	0x00000000
0xA080_001C	DMA Channel 2 Peripheral Chip Select	R/W	0x00000000

## DMA Buffer Descriptor Pointer

**Address:** A080\_0000, A080\_0010

The DMA Buffer Descriptor Pointer register contains a 32-bit pointer to the first buffer in a contiguous list of buffer descriptors.

The external DMA module has two of these registers. Each buffer descriptor is 16 bytes in length.

Register

Register bit assignment

Bit(s)	Access	Mnemonic	Reset	Description
D31:00	R/W	BuffDesc	0x0000_0000	32-bit pointer to a buffer descriptor

DMA Control register

Address: A080\_0004, A080\_0014

The DMA Control register contains the required DMA transfer control information. The external DMA module has two of these registers.

Register

## Register bit assignment

Bit(s)	Access	Mnemonic	Reset	Description
D31	R/W	CE	0	<b>Channel enable</b> Enables and disables DMA operations as required. After a DMA channel has entered the IDLE state for any reason, this field must be written to a 1 to initiate further DMA transfers.
D30	R/W	CA	0	<b>Channel abort</b> When set, causes the current DMA operation to complete and closes the buffer.
D29	R/W	CG	0	<b>Channel go</b> When set, causes the DMA channel to exit the IDLE state and begin a DMA transfer. The CE field 31) must also be set, which allows software to initiate a memory-to-memory transfers. The dma_req and dma_done signals are not used during memory-to-memory transfers.
D28:27	R/W	SW	0	<b>Source width</b> Defines the data bus width of the device attached to the source address specified in the buffer descriptor. 00    8 bit 01    16 bit 10    32 bit 11    Reserved
D26:25	R/W	DW	0	<b>Destination width</b> Defines the data bus width of the device attached to the destination address specified in the buffer descriptor. 00    8 bit 01    16 bit 10    32 bit 11    Reserved
D24:23	R/W	SB	0	<b>Source burst</b> Defines the AHB maximum burst size allowed when reading from the source. Note that the source must have enough data, as defined by this register setting, before asserting REQ. 00    1 unit as set by the source width field (D28:27) 01    4 bytes (Recommended for 8-bit devices) 10    16 bytes (Recommended for 16-bit devices) 11    32 bytes (Recommended for 32-bit devices)

Bit(s)	Access	Mnemonic	Reset	Description
D22:21	R/W	DB	0	<b>Destination burst</b> Defines the AHB maximum burst size allowed when writing to the destination. Note that the destination must have enough space, as defined by this register setting, before asserting REQ. 00 1 unit as set by the destination width field (D26:25) 01 4 bytes (Recommended for 8-bit devices) 10 16 bytes (Recommended for 16-bit devices) 11 32 bytes (Recommended for 32-bit devices)
D20	R/W	SINC_N	0	<b>Source address increment</b> Controls whether the source address pointers are incremented after each DMA transfer. The DMA controller uses these bits in all modes whenever referring to a memory address. 0 Increment source address pointer 1 Do not increment source address pointer
D19	R/W	DINC_N	0	<b>Destination address increment</b> Controls whether the destination address pointers are incremented after each DMA transfer. The DMA controller uses these bits whenever referring to a memory address. 0 Increment destination address pointer 1 Do not increment destination address pointer
D18	R/W	POL	0	<b>Control signal polarity</b> Defines the active polarity of the dma_req, dma_done, and PDEN signals. 0 Active high signals 1 Active low signals
D17	R/W	MODE	0	<b>Fly-by mode</b> Defines the direction of data movement for fly-by DMA transfers. 0 Peripheral-to-memory fly-by-write DMA transfer 1 Memory-to-peripheral fly-by-read DMA transfer Note: This field is not used for DMA transfers initiated by writing a 1 to the CG field in this register (D29).

## EXTERNAL DMA

### DMA Status and Interrupt Enable register

Bit(s)	Access	Mnemonic	Reset	Description
D16	R/W	RST	0	<b>Reset</b> Forces a reset of the DMA channel. Writing a 1 to this field forces all fields in this register, <i>except the index field</i> , to the reset state. The reset field is written with the value specified on signals HWDATA[9:0]. This field always reads back a 0. Note: Writing a 1 to this field while the DMA channel is operational will have unpredictable results.
D15:10	R	STATE	0	<b>State</b> 0 Idle 1-3 Buffer descriptor read 4-7 Data transfer 8-12 Buffer descriptor update 13 Error
D09:00	R/W	INDEX	0	<b>Index</b> Identifies the current 16-byte offset pointer relative to the buffer descriptor pointer. Note: This field can be written to only when the RST field (D16) is being written to a 1.

## DMA Status and Interrupt Enable register

Address: A080\_0008, A080\_0018

The DMA Status and Interrupt Enable register contains the DMA transfer status and control information used in generating AHB DMA interrupt signals. The external DMA module has two of these registers.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
NCIP	ECIP	NRIP	CAIP	PCIP	Not used		NCIE	ECIE	NRIE	CAIE	PCIE	WRAP	DONE	LAST	FULL
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BLEN															

## Register bit assignment

Bit(s)	Access	Mnemonic	Reset	Description
D31	R/W1C	NCIP	0	<b>Normal completion interrupt pending</b> Set when a buffer descriptor has been closed. A normal DMA channel completion occurs when the BLEN count (D15:00) expires to zero and the L bit in the buffer descriptor is set or when the peripheral device signals completion.
D30	R/W1C	ECIP	0	<b>Error completion interrupt pending</b> Set when the DMA channel encounters either a bad buffer descriptor pointer or a bad data buffer pointer. When the ECIP bit is set, the DMA channel stops until the ECIP bit is cleared by firmware. The DMA channel does not advance to the next buffer descriptor. When firmware clears the ECIP bit, the buffer descriptor is retried from where it left off. The CA bit in the DMA Control register can be used to abort the current buffer descriptor and advance to the next descriptor.
D29	R/W1C	NRIP	0	<b>Buffer not ready interrupt pending</b> Set when the DMA channel encounters a buffer descriptor whose F bit is in the incorrect state. The F bit must be set in order for the fetched buffer descriptor to be considered valid. If the F bit is not set, the descriptor is considered invalid and the NRIP field is set. When the NRIP bit is set, the DMA channel stops until the field is cleared by firmware. The DMA channel does not advance to the next buffer descriptor.
D28	R/W1C	CAIP	0	<b>Channel abort interrupt pending</b> Set when the DMA channel detects the CA bit (D30) set in the DMA Control register. When CAIP is set, the DMA channel stops until the CAIP bit is cleared by firmware. The DMA channel automatically advances to the next buffer descriptor after CAIP is cleared. The CA bit in the DMA Control register must be cleared, through firmware, before the CAIP bit is cleared. Failure to reset the CA bit cause the next buffer descriptor to abort also.
D27	R/W1C	PCIP	0	<b>Premature complete interrupt pending</b> Set when a DMA transfer is terminated by assertion of the dma_done signal. NCIP is set when PCIP is set for backwards compatibility.
D26:25	R/W	Not used	0	This field must always be set to 0.

Bit(s)	Access	Mnemonic	Reset	Description
D24	R/W	NCIE	0	Enable NCIP interrupt generation.
D23	R/W	ECIE	0	Enable ECIE interrupt generation. This interrupt should always be enabled during normal operation.
D22	R/W	NRIE	0	Enable NRIP interrupt generation.
D21	R/W	CAIE	0	Enable CAIP interrupt generation. This interrupt should always be enabled during normal operation.
D20	R/W	PCIE	0	Enable PCIP interrupt generation.
D19	R	WRAP	0	<i>Read-only</i> debug field that indicates the last descriptor in the descriptor list.
D18	R	DONE	0	<i>Read-only</i> debug field that indicates the status of the DONE signal.
D17	R	LAST	0	<i>Read-only</i> debug field that indicates the last buffer descriptor in the current data frame.
D16	R	FULL	0	<i>Read-only</i> debug field that indicates the status of the F bit from the current DMA buffer descriptor.
D15:00	R	BLN	0	<i>Read-only</i> debug field that indicates the current byte transfer count.

## DMA Peripheral Chip Select register

Address: A080\_000C, A080\_001C

The DMA Peripheral Chip Select register contains the DMA channel peripheral chip select definition. The external DMA module has two of these registers.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Not used

Not used														SEL	

## Register bit assignment

Bit(s)	Access	Mnemonic	Reset	Definition
D31:02	R/W	Not used	0	This field must always be set to 0.
D01:00	R/W	SEL	0	<b>Chip select</b> Defines which of the four memory interface chip select signals (nmpmcstcsout[n]) is connected to the external peripheral. 00 nmpmcstcsout[0] 01 nmpmcstcsout[1] 10 nmpmcstcsout[2] 11 nmpmcstcsout[3]

# *AES Data Encryption/Decryption Module*

## C H A P T E R 8

The AES data encryption/decryption module provides IPsec-compatible network security to processor-based systems. The AES core module implements Rijndael encoding/decoding in compliance with the NIST Advanced Encryption Standard (AES).

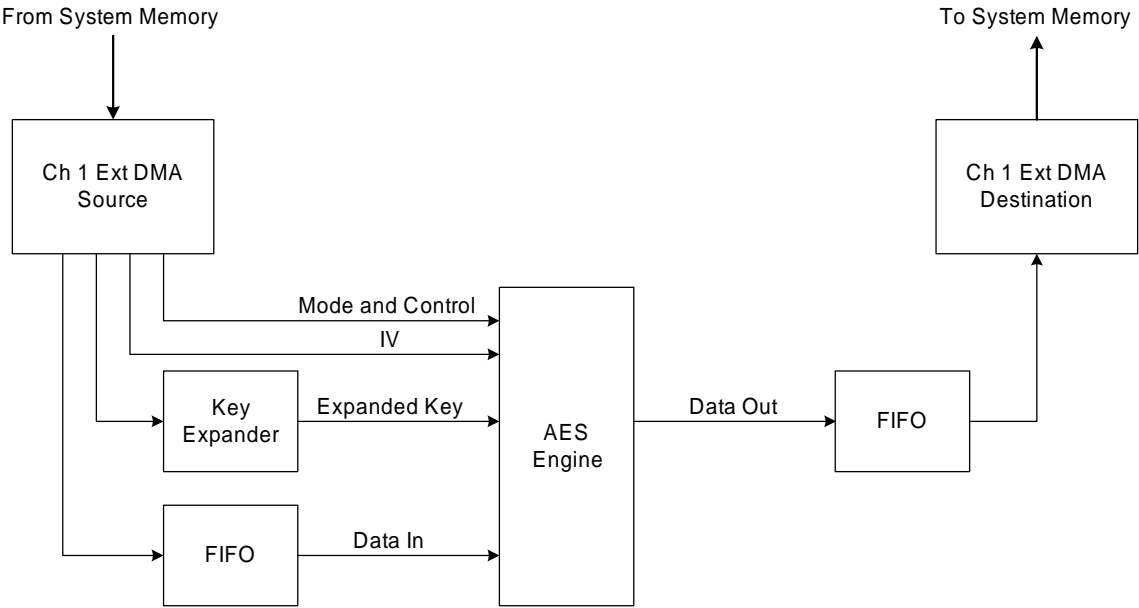

### Features

- Processes 32 bits at a time.
- Is programmable for 128-, 192-, or 256-bit key lengths.
- Supports ECB, CBC, OFB, CTR, and CCM cipher modes.
- Implements a hardware key expander to minimize software intervention during the encryption/decryption process. During encryption and decryption, the key expander can produce the expanded key on the fly.
- Exists behind external DMA channel 1 (see Chapter 7, “External DMA,” for information about DMA control registers and programming).
- Uses the buffer descriptor control field to indicate a memory-to-memory AES operation.

**Note:** The encryption engine operates in little endian mode. If the system is operating in big endian mode, the data buffers must be byte swapped before and after each encryption/decryption operation. If using NetOS, the byte swapping is handled by software.

Block diagram

Data blocks

The AES module works on 128-bit blocks of data. This table shows the performance per each 128-bit block, depending on the key size:

Characteristic	Key size		
	128	192	256
Number of cycles	44	52	60
Latency (cycles)	44	52	60
Throughput (bits/cycles)	~2.90	~2.46	~2.13
Throughput @ 75 MHz (MegaBytes/sec)	~27.19	~23.06	~19.97

AES DMA buffer descriptor

.....

The AES DMA buffer descriptor is the same as the external DMA buffer descriptor, with the exception of the control bits – AES op and AES control.

**AES buffer descriptor diagram**

	31	30	29	28		16	15		0
OFFSET + 0	Source address								
OFFSET + 4	Destination buffer length						Source buffer length		
OFFSET + 8	Destination address								
OFFSET + C	W	I	L	F	Reserved	AES Op	AES control		

Field definitions follow.

**Source address [pointer]**

The source address pointer identifies the starting location of the source data. The source address can be aligned to any byte boundary.

**Note:** Optimal performance is achieved when the source address is aligned on a word boundary.

**Source buffer length**

The source buffer length indicates the number of bytes to be read from the source. After completing the transfer, the DMA controller updates this field with the actual number of bytes that were moved. This is useful for debugging error conditions or determining the number of bytes transferred before the DONE signal was asserted.

**Destination buffer length**

The destination buffer length indicates the number of bytes to be written to the destination. This field should be identical to the source buffer length for all modes — with the exception of CCM — when the authentication code is being generated or a key is being expanded.

**Destination address [pointer]**

The destination address pointer field identifies the starting location of the source data's destination; that is, to where the source data needs to be moved. The destination address must be word-aligned.

**AES control**

Bits	Used for	Values	
[2:0]	Encryption mode select	000	CBC
		001	CFB
		010	OFB
		011	CTR
		100	ECB
		101	CCM
		111	Key expand mode, which allows a key to be expanded by the hardware key expander and written back to system memory
[3]	Encryption/decryption select	0	Encryption
		1	Decryption

Bits	Used for	Values
[5:4]	Key size	00 128 bits
		01 192 bits
		10 256 bits
[6]	Additional authentication data (CCM mode only)	0 No additional data
		1 Additional data used
[9:7]	L-par (CCM mode only)	N/A
[10]	Reserved	N/A
[13:11]	M-par (CCM mode only)	N/A
[15:14]	Reserved	N/A

### **AES op code**

Indicates the contents of the data buffer associated with this descriptor:

- 000 Non-AES memory-to-memory or external DMA mode
- 001 Key buffer
- 010 IV buffer
- 011 Nonce buffer (CCM mode only, 16 bytes fixed length)
- 100 Additional authentication data (CCM mode only)
- 101 Data to be encrypted or decrypted

### **WRAP (W) bit**

The Wrap (W) bit, when set, tells the DMA controller that this is the last buffer descriptor within the continuous list of descriptors. The next buffer descriptor is found using the initial DMA channel buffer descriptor pointer. When the W bit is not set, the next buffer descriptor is found using an offset of 0x10 from the current buffer descriptor.

### **Interrupt (I) bit**

The Interrupt bit, when set, tells the DMA controller to issue an interrupt to the CPU when the buffer is closed due to a normal channel completion. The interrupt occurs regardless of the normal completion interrupt enable configuration for the DMA channel.

### **Last (L) bit**

The Last bit, when set, tells the DMA controller that this buffer descriptor is the last descriptor that completes an entire message frame. The DMA controller uses this bit to assert the normal channel completion status when the byte count reaches zero.

### **Full (F) bit**

The Full bit, when set, indicates that the buffer descriptor is valid and can be processed by the DMA channel. The DMA channel clears this bit after completing the transfer(s).

The DMA channel does not try a transfer when the F bit is clear. The DMA channel enters an idle state upon fetching a buffer descriptor with the F bit cleared.

When the F bit is modified by the device driver, the device driver must also write an 'I' to the CE bit (in the DMA Control register) to activate the idle channel.

## Decryption

During decryption, the expanded key must be fed to the AES core backwards. The hardware key expander can handle this, but the input key is different than for encryption. The key must be expanded and the last words must be written to the key buffer as shown:

- A 128-bit key (K0, K1, K2, K3) is expanded to the following 32-bit word sequence: K0, K1, ..., K40, K41, K42, K43.  
To expand the key backwards, the hardware key expander needs K40-K43.
- A 192-bit key (K0, K1, K2, K3, K5, K6) is expanded to the following 32-bit word sequence: K0, K1, ..., K46, K47, K48, K49, K50, K51.  
To expand the key backwards, the hardware key expander core needs K48-51 followed by K46-47.
- A 256-bit key (K0, K1, K2, K3, K5, K6, K7) is expanded to the following 32-bit word sequence: K0, K1, ..., K52, K53, K54, K55, K56, K57, K58, K59.  
To expand the key backwards, the hardware key expander core needs K56-59 followed by K52-55.

The hardware key expander recreates all the remaining words in backwards order.

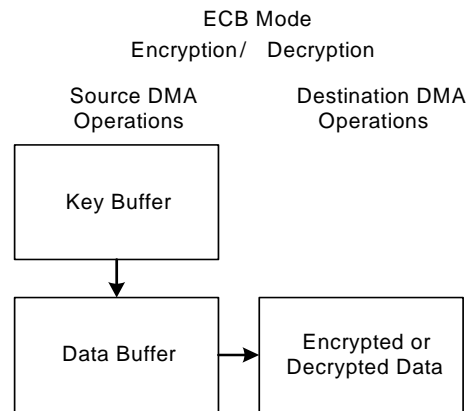

## ECB processing

ECB mode does not require an initialization vector. Software just needs to set up a key buffer descriptor, followed by a data buffer descriptor.

### Processing flow diagram

This is the ECB buffer descriptor processing flow:

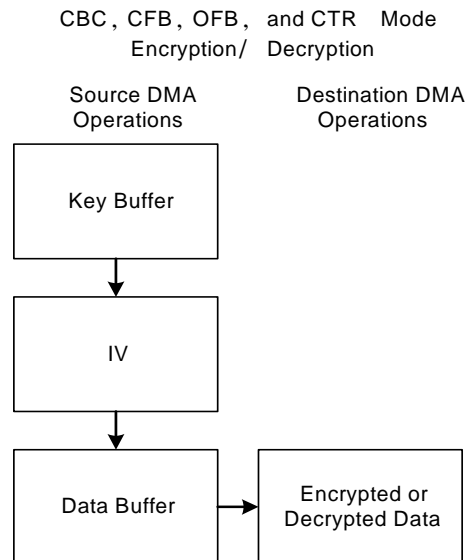

## CBC, CFB, OFB, and CTR processing

CBC, CFB, OFB, and CTR modes need an initialization vector. Software must set up this buffer descriptor sequence: Key, IV, Data.

### Processing flow diagram

This is the buffer descriptor processing flow for CBC, CFB, OFB, and CTR:

## CCM mode

CCM mode does not require an initialization vector.

- For encryption, software must set up this buffer descriptor sequence: Key, Nonce, additional data (optional), data (used to compute the authentication code), data (used to perform the actual encryption).
- For decryption, software must set up this buffer descriptor sequence: Key, Nonce, Data (used to perform the actual decryption), Additional data (optional), Data (used to compute the authentication code).

**Note:** The data must be DMA'ed through the AES module twice in CCM mode for both encryption and decryption modes.

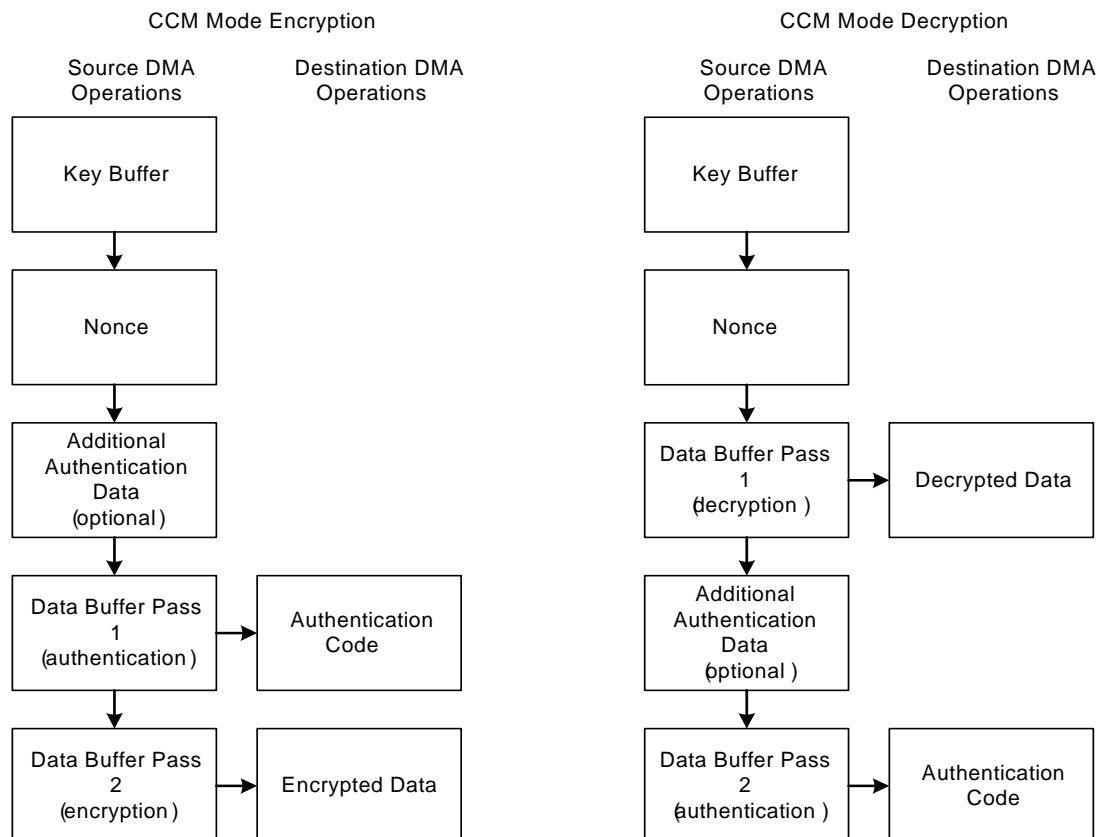

### Nonce buffer

This is the format of the Nonce buffer:

Bits	127:120	119:8*L-par	8*L-par-1:0
Contents	reserved	Nonce	Message length

### Processing flow

This is the CCM buffer descriptor processing flow:

# *I/O Hub Module*

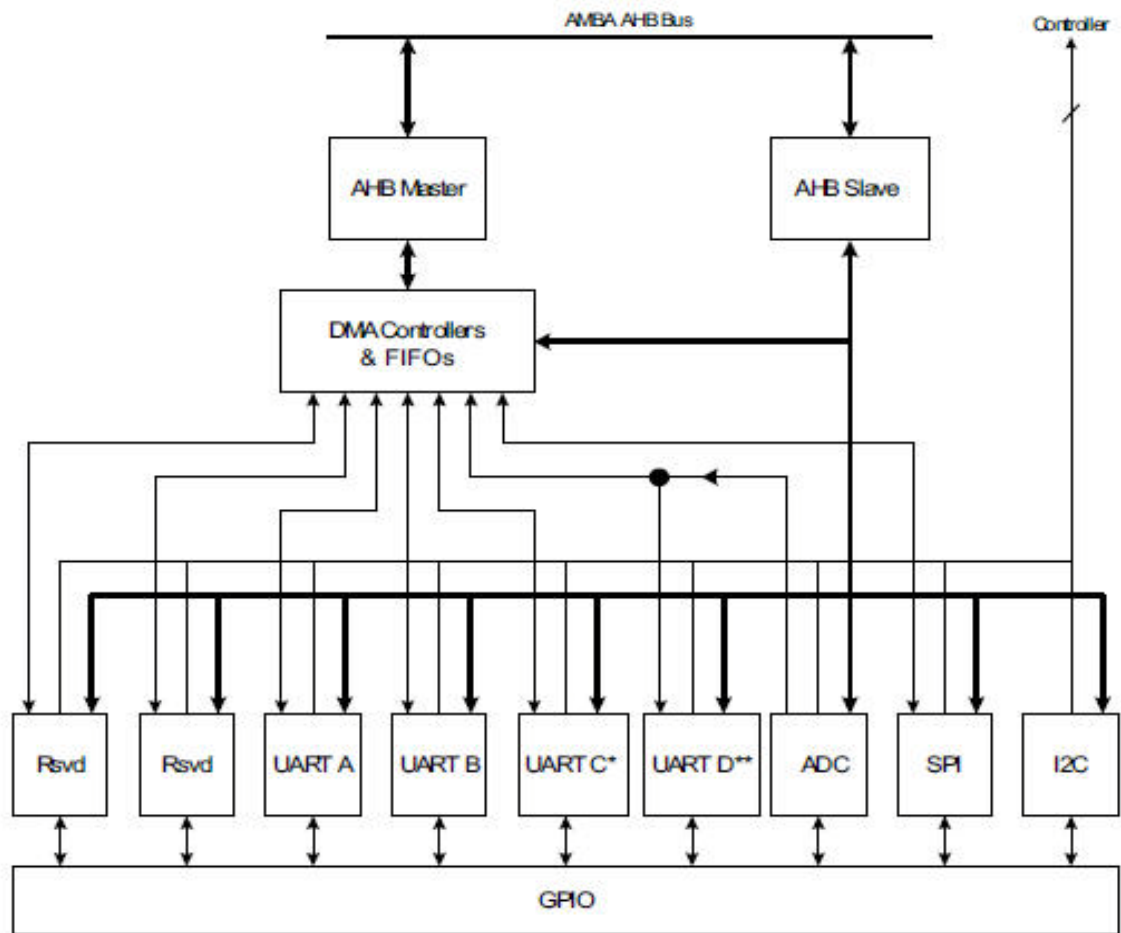

## C H A P T E R 9

The I/O hub provides access to the low speed ports on the processor through one master port on the AHB bus. The low speed ports include four UART ports, one SPI port, one I<sup>2</sup>C port, 2 Flexible Interface Modules (FIMs), and one analog-to-digital converter (ADC) port. UART channel C can be configured for HDLC operation.

The SPI, UARTs, and ADC port data transfers can be controlled either directly by the CPU or through the DMA controllers, which are integrated into the I/O hub. The I<sup>2</sup>C does not have DMA support.

## Block diagram

- \* HDLC capable
- \*\* DMA rx channel shared

### AHB slave interface

The CPU has access to the control and status registers in the DMA controller, the peripheral devices, and the GPIO configuration.

## DMA controller

The I/O Hub provides seven dual-channel DMA controllers to service the low speed peripherals. Each dual-channel controller has a transmit channel and a receive channel, each with a 64 byte Fifo.

### Servicing RX and TX FIFOs

The DMA controller services the RX and TX FIFOs in a round-robin manner. When one of the FIFOs needs servicing — that is, it can accept a burst of four 32-bit words —

the DMA controller requests the AHB bus through the AHB master. After the request has been granted, the peripheral buffer data is transferred to or from system memory.

**Buffer descriptors** The peripheral buffer data is held in buffers in external memory, linked together using buffer descriptors. The buffer descriptors are 16 bytes in length and are located contiguously in external memory.

This is the format of the buffer descriptor:

Address		Description	
offset + 0	Source address		
offset + 4	Reserved	Buffer length	
offset + 8	Reserved		
offset + C	Control	Status	
	31	16	150

**Source address [pointer]** The source address pointer points to the start of the buffer in system memory.

- For transmit channels, the address can start on any byte boundary.
- For receive channels, the address must be a 32-bit word aligned.

**Buffer length** The buffer length is the length of the buffer in bytes, and allows a buffer size of up to 64k-1 bytes to be in a single buffer. Bits 31:16 are not used.

For receive channels, the buffer length field is updated with the actual number of bytes written to memory, as the peripheral has the ability to close the buffer early.

**Control[15] – W** The Wrap (W) bit, when set, tells the DMA controller that this is the last buffer descriptor within the continuous list of descriptors. The next descriptor is found using the initial DMA channel buffer descriptor pointer. When the W bit is not set, the next buffer descriptor is found using the 16-byte offset.

**Control[14] – I** The Interrupt (I) bit, when set, tells the DMA controller to issue an interrupt when the buffer is closed due to normal channel completion.

**Control[13] – L** This is the Last (L) bit.

- For transmit channels, firmware sets the L bit when the current buffer is the last in the packet.

- For receive channels. hardware sets the L bit when the current buffer is closed by status bits received from the peripheral device. Status bits can include conditions such as a character gap timeout, character match, or error condition.

**Control[12] – F**

This is the Full (F) bit.

- For transmit channels. CPU sets the F bit after the data is written to a buffer. The DMA controller clears this bit as each buffer is read from external memory. If the DMA controller ever finds that this bit is not set when the buffer descriptor is read, the NRIP bit is set in the Interrupt Status register and the DMA controller stops immediately and goes to the ERROR state. The CPU must clear the CE bit to restore the DMA.
- For receive channels, hardware sets the F bit after data is written to a buffer. The CPU must clear the F bit after all data has been read from the buffer. If the DMA controller ever finds that this bit is not clear when the buffer descriptor is read, the NRIP bit is set in the Interrupt Status register and the DMA controller stops immediately.  
  
The DMA controller must be soft reset after the buffer descriptor problem has been solved.

**Control[11:0]**

These bits are not used.

**Status[15:0]**

The status depends on the module, as defined in the next tables.

**Note:** In direct mode, the status can be read from the Direct Mode RX Status FIFO.

**UART**

Bits	Description
15:7	Reserved
6:5	01 Error; bits 3:0 indicate the error type bit 4: Reserved bit 3: Receiver overflow, should never occur in a properly configured system bit 2: Parity error bit 1: Framing error bit 0: Break condition

HDLC

Bits	Description
15:7	Reserved
6:5	01 HDLC frame close, bits 3:0 indicate the close condition bit 4: The last byte is less than 8 bits bit 3: Receiver overflow, should never occur in a properly configured system bit 2: Invalid CRC found at end of frame bit 1: Valid CRC found at end of frame bit 0: Abort condition found 11 match character found bit 4: Match character 4 bit 3: Match character 3 bit 2: Match character 2 bit 1: Match character 1 bit 0: Match character 0 00 Other close event bit 2: Buffer gap timer expired bit 1: Software-initiated buffer close

SPI

Not applicable.

Transmit DMA example

After the last buffer in the data packet has been placed in system memory and the buffer descriptors have been configured, the data packet is ready to be transmitted. The CPU configures the module DMA TX buffer descriptor pointer, TXBDP (see “[Module] DMA TX Buffer Descriptor Pointer” on page 382), and then sets the channel enable bit in the DMA Control register.

Process

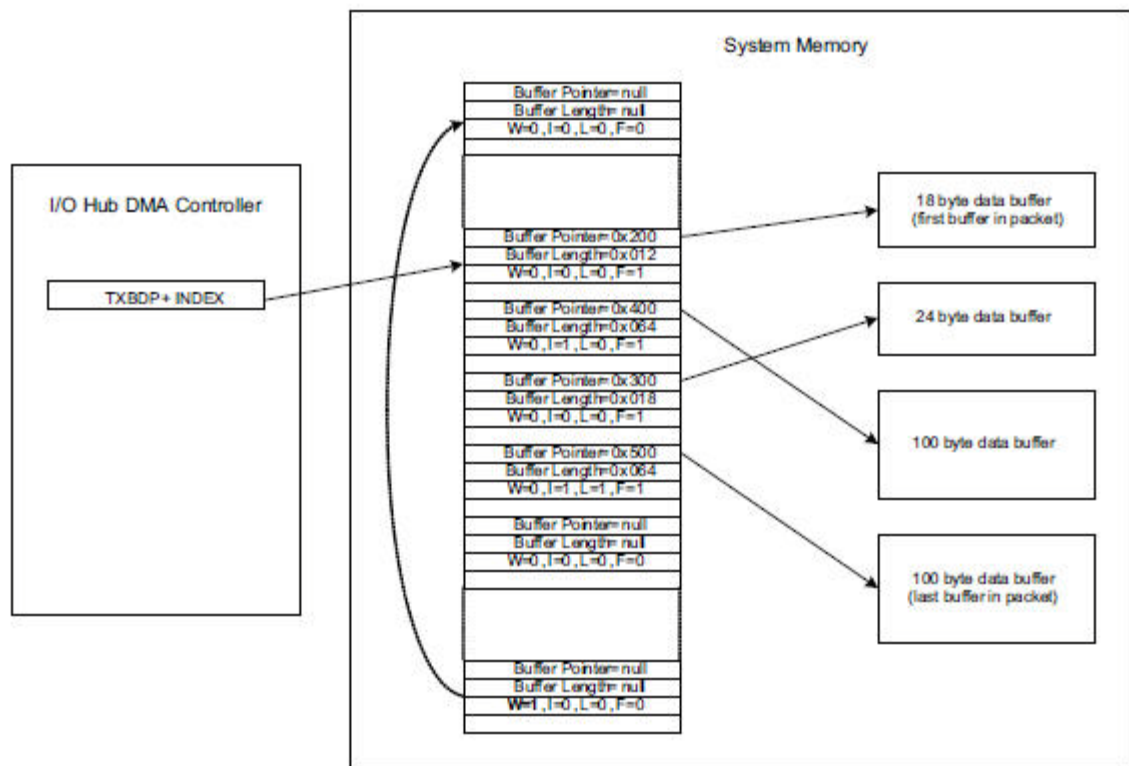

The DMA controller starts the process to read the buffer descriptor and buffer data from system memory using the AHB master. The DMA controller follows this process:

- 1 Reads the first buffer descriptor, as pointed to by the TX buffer descriptor pointer and INDEX.

- 2 Verifies that the data buffer is valid by making sure the F bit is set to 1.
- 3 Reads the first data buffer, in 16-byte bursts.
- 4 Continues to process the buffer descriptors and data buffers until all data has been transmitted from the buffer descriptor with the L bit set to 1. The DMA controller interrupts the CPU if the I bit is set to a 1.
- 5 Remains in the IDLE state until the channel enable bit is set to a 0, then set to a 1 again.

### Visual example

## Control and status register address maps

The I/O Hub provides a series of registers for the low speed peripheral modules it supports. The DMA, direct mode, and interrupt control register formats are the same for these modules. The base address for the registers is 0x9000\_0000. Write buffering in the MMU must be disabled for all registers in the I/O Hub address space, from address 0x9000\_0000 to 0x9FFF\_FFFF.

Register address maps are shown for each low speed peripheral module.

**Note:** Registers 9000\_0000 - 9000\_7FFF and registers 9000\_8000 - 9000\_FFFF are reserved.

### UART A register address map

Register Offset	Description (31:00)
0x9001_0000	UART A Interrupt and FIFO Status
0x9001_0004	UART A DMA RX Control

### I<sup>2</sup>C register address map

Register Offset	Description (31:00)
0x9005_0000 – 0x9005_7FFF	I <sup>2</sup> C CSR Space

### Reserved

Registers 9005\_8000 - 9005\_FFFF are reserved.

**RTC register  
address map**

Register Offset	Description (31:00)
0x9006_00C0 – 0x9006_00FC	64-byte Battery Backed RAM

**IO Hardware  
Assist register  
address map (0)**

Register Offset	Description (31:00)
0x9006_8000 – 0x9006_FFFF	IO Hardware Assist CSR Space for Flexible Interface Module 0

**IO Hardware  
Assist register  
address map (1)**

Register Offset	Description (31:00)
0x9007_0000 – 0x9007_7FFF	IO Hardware Assist CSR Space for Flexible Interface Module 1

**IO register  
address map (0)**

Register Offset	Description (31:00)
0x9008_0000 – 0x9008_FFFF	IO Space for Flexible Interface Module 0

**IO register  
address map (1)**

Register Offset	Description (31:00)
0x9009_0000 – 0x9009_FFFF	IO Space for Flexible Interface Module 1

**[Module] Interrupt and FIFO Status register****Addresses:**

FIM 0 9000_0000	FIM 1 9000_8000
UART A 9001_0000	UART B 9001_8000
UART C 9002_0000	UART D 9002_8000*
SPI 9003_0000	ADC 9003_8000*

\*UART and ADC use different addresses but access the same shared DMA/FIFO.

The Interrupt and FIFO Status register allows software to determine the cause of the current low speed peripheral interrupts and to clear the interrupt bit.

**Note:** An access type of R/W\* means that the processor must write 1 to clear the value if the read value is 1. If the read value is 0, the write value must be 0.

## Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RXPB USY	RX FIFO full	RX FIFO empty	TXPB USY	TX FIFO full	TX FIFO empty	Reserved									

## Register bit assignment

Bit(s)	Access	Mnemonic	Reset	Description
D31	R/W*	RXNCIP	0x0	<b>Normal completion interrupt pending (RX)</b> Set when a buffer is closed under normal conditions. An interrupt is generated when the I bit is set in the current buffer descriptor. A normal DMA completion occurs when the buffer length field expires.
D30	R/W*	RXECIP	0x0	<b>Error completion interrupt pending (RX)</b> Set when the DMA channel finds either a bad buffer descriptor or a bad data buffer pointer. The DMA channel remains in the ERROR state until the CE bit in the DMA Control register is cleared and then set again. The DMA channel then uses the buffer descriptor as set in the index control field.
D29	R/W*	RXNRIP	0x0	<b>Buffer not ready interrupt pending (RX)</b> Set when the DMA channel finds a buffer descriptor with the F bit not set. The DMA channel remains in the ERROR state until the CE bit is set in the DMA Control register is cleared and then set again.
D28	R/W*	RXCAIP	0x0	<b>Channel abort interrupt pending (RX)</b> Set when the DMA channel finds the channel abort (CA) bit set. The DMA controller closes the current buffer descriptor and remains in the IDLS state until the CA bit is cleared and the CE bit is set.
D27	R/W*	RXPCIP	0x0	<b>Premature completion interrupt pending</b> Set when a buffer descriptor is closed by the peripheral instead of by reaching the buffer length. The DMA channel continues processing buffer descriptors

Bit(s)	Access	Mnemonic	Reset	Description
D26	R/W*	RXFOFIP	0x0	<b>RX FIFO overflow interrupt pending</b> Set when the RX FIFO finds an overflow condition.
D25	R/W*	RXFSRIP	0x0	<b>RX FIFO service request interrupt pending (RX)</b> Set when the RX FIFO level rises above the receive FIFO threshold (in the RX Interrupt Configuration register).
D24	R/W*	TXNCIP	0x0	<b>Normal completion interrupt pending (TX)</b> Set when a buffer is closed under normal conditions. An interrupt is generated when the I bit is set in the current buffer descriptor. A normal DMA completion occurs when the buffer length field expires.
D23	R/W*	TXECIP	0x0	<b>Error completion interrupt pending (TX)</b> Set when the DMA channel finds either a bad buffer descriptor or a bad data buffer pointer. The DMA channel remains in the ERROR state until the CE bit in the DMA Control register is cleared and then set again. The DMA channel then uses the buffer descriptor as set in the index control field.
D22	R/W*	TXNRIP	0x0	<b>Buffer not ready interrupt pending (TX)</b> Set when the DMA channel finds a buffer descriptor with the F bit not set. The DMA channel remains in the ERROR state until the CE bit in the DMA Control register is cleared and then set again. The DMA channel then uses the buffer descriptor as set in the index control field.
D21	R/W*	TXCAIP	0x0	<b>Channel abort interrupt pending (TX)</b> Set when the DMA channel finds the channel abort (CA) control bit set. The DMA controller closes the current buffer descriptor and remains in the IDLE state until the CA bit is cleared and the CE bit is set.
D20	R/W*	TXFUFIP	0x0	<b>TX FIFO underflow interrupt pending</b> Set when the TX FIFO finds an underflow.
D19	R/W*	TXFSRIP	0x0	<b>TX FIFO service request interrupt pending (TX)</b> Set when the TX FIFO level drops below the transmit FIFO threshold (in the TX Interrupt Configuration register).

Bit(s)	Access	Mnemonic	Reset	Description
D18	R	MODIP	0x0	<b>Module interrupt pending</b> The hardware module has asserted an interrupt. Software must read the appropriate Interrupt Status register to determine the cause.
D17:16	N/A	Reserved	N/A	N/A
D15	R	RXPBUSY	0x0	0 Peripheral idle 1 Peripheral busy Note: Applicable only for channels connected to the flexible I/O module processors. The CPU when connected to FIM processors must not access the Module Direct Mode RX Data FIFO Read register when this bit is set. If this bit is set, the read generates a bus error.
D14	R	RX_FIFO_full	0x0	<b>Receive status and data FIFO full status</b> 0 Not full 1 Full
D13	R	RX_FIFO_empty	0x1	<b>Receive status and data FIFO empty status</b> 0 Not empty 1 Empty
D12	R	TXPBUSY	0x0	0 Peripheral idle 1 Peripheral busy Note: Applicable only for channels connected to the flexible I/O module processors. The CPU when connected to FIM processors must not access the Module Direct Mode TX Data FIFO register when this bit is set. If this bit is set, the read generates a bus error.
D11	R	TX_FIFO_full	0x0	<b>Transmit data FIFO full status</b> 0 Not full 1 Full
D10	R	TX_FIFO_empty	0x1	<b>Transmit data FIFO empty status</b> 0 Not empty 1 Empty
D09:00	N/A	Reserved	N/A	N/A

## [Module] DMA RX Control

### Addresses:

FIM 0 9000_0004	FIM 1 9000_8004
UART A 9001_0004	UART B 9001_8004
UART C 9002_0004	UART D 9002_8004*
SPI 9003_0004	ADC 9003_8004*

\* UART and ADC use different addresses but access the same shared DMA/FIFO.

The DMA RX Control register contains control register settings for each receive DMA channel.

### Register

### Register bit assignment

Bit(s)	Access	Mnemonic	Reset	Description
D31	R/W	CE	0x0	<b>Channel enable</b> 0 Disable DMA operation 1 Enable DMA operation
D30	R/W	CA	0x0	<b>Channel abort</b> When set, causes the current DMA operation to complete and closes the buffer. The DMA channel remains idle until this bit is cleared.
D29	R/W	FIM	0x0	0 DMA controlled by CPU 1 DMA controlled by FIM This bit is valid only for channels 0 and 1, which are assigned to FIM 0 and FIM 1.
D28	R/W	DIRECT	0x0	0 DMA mode 1 Direct access mode
D27:16	N/A	Reserved	N/A	N/A

Bit(s)	Access	Mnemonic	Reset	Description
D15:10	R	STATE	0x0	DMA state machine status field
D09:00	R	INDEX	0x0	This field can be read at any time to determine the current index.

## [Module] DMA RX Buffer Descriptor Pointer

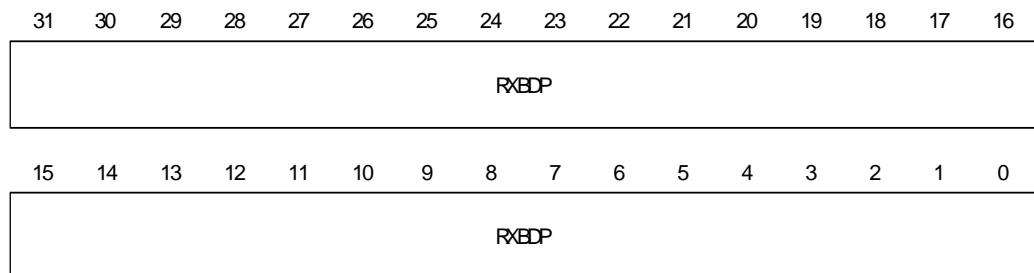

### Addresses:

FIM 0 9000_0008	FIM 1 9000_8008
UART A 9001_0008	UART B 9001_8008
UART C 9002_8008	UART D 9002_8008*
SPI 9003_0008	ADC 9003_8008*

\*UART D and ADC use different addresses but access the same shared DMA/FIFO.

The DMA RX Buffer Descriptor Pointer register is the address of the first buffer descriptor for each DMA channel.

### Register

### Register bit assignment

Bit(s)	Access	Mnemonic	Reset	Description
D31:00	R/W	RXBDP	0x0	The first buffer descriptor in the ring. Used when the W bit is found, which indicates the last buffer descriptor in the list.

## [Module] RX Interrupt Configuration register

### Addresses:

FIM 0 9000_000C	FIM 1 9000_800C
UART A 9001_000C	UART B 9001_800C
UART C 9002_000C	UART D 9002_800C*
SPI 9003_000C	ADC 9003_800C*

\*UART D and ADC use different addresses but access the same shared DMA/FIFO.

The RX Interrupt Configuration register allows system software to configure the interrupt for the I/O hub module receive channel.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

BLENSTAT															

### Register bit assignment

Bit(s)	Access	Mnemonic	Reset	Description
D31:28	R/W	RXTHRS	0xF	<b>RX FIFO threshold</b> An interrupt is generated when the number of 32 bit words in the FIFO rises above this level.
D27	N/A	Reserved	N/A	N/A
D26	R/W	RXFOFIE	0x0	Enable the RXFOFIP interrupt.
D25	R/W	RXFSRIE	0x0	Enable the RXFSRIP interrupt.
D24	R/W	RXNCIE	0x0	Enable the RXNCIP interrupt.
D23	R/W	RXECIE	0x0	Enable the RXECIP interrupt.
D22	R/W	RXNRIE	0x0	Enable the RXNRIP interrupt.
D21	R/W	RXCAIE	0x0	Enable the RXCAIP interrupt.
D20	R/W	RXPCIE	0x0	Enable the RXPCIP interrupt.
D19	R	WSTAT	0x0	Debug field, indicating the W bit is set in the current buffer descriptor.

Bit(s)	Access	Mnemonic	Reset	Description
D18	R	ISTAT	0x0	Debug field, indicating the I bit is set in the current buffer descriptor.
D17	R	LSTAT	0x0	Debug field, indicating the L bit is set in the current buffer descriptor.
D16	R	FSTAT	0x0	Debug field, indicating the F bit is set in the current buffer descriptor.
D15:00	R	BLENSTAT	0x0	Debug field, indicating the current byte count.

## [Module] Direct Mode RX Status FIFO

### Addresses:

FIM 0 9000_0010	FIM 1 9000_8010
UART A 9001_0010	UART B 9001_8010
UART C 9002_0010	UART D 9002_8010*
SPI 9003_0010	ADC 9003_8010*

\*UART D and ACD use different addresses but access the same shared DMA/FIFO.

The Direct Mode RX Status FIFO register is used when in direct mode of operation, to determine the status of the receive FIFO.

- This register must be read before each read to the RX Data FIFO register.
- The RX Data FIFO register must be read after each read to this register, even if the BYTE field is 0.

### Register

### Register bit assignment

Bit(s)	Access	Mnemonic	Reset	Description
D31:12	N/A	Reserved	N/A	N/A
D11:09	R	BYTE	N/A	Number of bytes in the current 32-bit location.
D08	N/A	Reserved	N/A	N/A
D07	R	FFLAG	N/A	<b>Full flag</b> Indicates that the FIFO went full when the current location was written.
D06:00	R	PSTAT	N/A	General peripheral status, unique to the peripheral attached to the channel.

## *[Module] Direct Mode RX Data FIFO*

### Addresses:

FIM 0 9000_0014	FIM 1 9000_8014
UART A 9001_0014	UART B 9001_8014
UART C 9002_0014	UART D 9002_8014*
SPI 9003_0014	ADC 9003_8014*

\*UART D and ADC use different addresses but access the same shared DMA/FIFO.

The Direct Mode RX Data FIFO register is used when in direct mode of operation, to read the RX Data FIFO.

**Note:** The Module Direct Mode RX FIFO Status register must be read before this register is read, to determine the valid number of bytes in the 32-bit access. The data is packed in little endian format.

### Register

## Register bit assignment

Bit(s)	Access	Mnemonic	Reset	Description
D31:00	R	RXD	N/A	RX Data FIFO Read register

## [Module] DMA TX Control

### Addresses:

## Register bit assignment

Bit(s)	Access	Mnemonic	Reset	Description
D31	R/W	CE	0x0	<b>Channel enable</b> 0 Disable DMA operation 1 Enable DMA operation
D30	R/W	CA	0x0	<b>Channel abort</b> When set, causes the current DMA operation to complete and closes the buffer. The DMA channel remains idle until this bit is cleared.
D29	R/W	FIM	0x0	0 DMA controlled by CPU 1 DMA controlled by FIM This bit is valid only for channels 0 and 1, which are assigned to FIM 0 and FIM 1.

Bit(s)	Access	Mnemonic	Reset	Description
D28	R/W	DIRECT	0x0	0 DMA mode 1 Direct access mode
D27	R/W	INDEXEN	0x0	0 Hardware will not use the INDEX field when in the idle state 1 Hardware will use the INDEX field when in the idle state
D26:16	N/A	Reserved	N/A	N/A
D15:10	R	STATE	0x0	DMA state machine status field
D09:00	R/W	INDEX	0x0	When the state machine is in the idle state, this register can be used to change the index. This field can be read at any time to determine the current index.

## [Module] DMA TX Buffer Descriptor Pointer

### Addresses:

FIM 0 9000_001C	FIM 1 9000_801C
UART A 9001_001C	UART B 9001_801C
UART C 9002_001C	UART D 9002_801C*
SPI 9003_001C	ADC 9003_801C*

\*UART D and ADC use different addresses but access the same shared DMA/FIFO.

The DMA TX Buffer Descriptor Pointer is the address of the first buffer descriptor for each DMA channel.

### Register

## Register bit assignment

Bit(s)	Access	Mnemonic	Reset	Description
D31:00	R/W	TXBDP	0x0	The first buffer descriptor in the ring. Used when the W bit is found, which indicates the last buffer descriptor in the list.

## [Module] TX Interrupt Configuration register

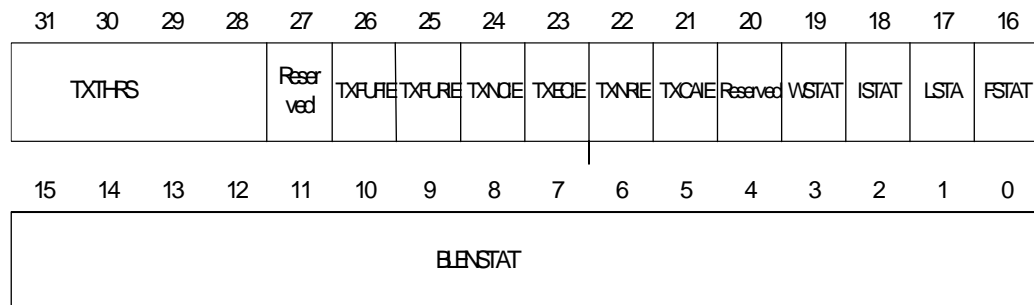

## Addresses:

FIM 0 9000_0020	FIM 1 9000_8020
UART A 9001_0020	UART B 9001_8020
UART C 9002_0020	UART D 9002_8020*
SPI 9003_0020	ADC 9003_8020*

\*UART D and ADC use different addresses but access the same shared DMA/FIFO.

The TX Interrupt Configuration register allows system software to configure the interrupt from the I/O hub module transmit channel.

## Register

## Register bit assignment

Bit(s)	Access	Mnemonic	Reset	Description
D31:28	R/W	TXTHRS	0xF	<b>TX FIFO threshold</b> An interrupt is generated when the FIFO level drops below this level.
D27	N/A	Reserved	N/A	N/A
D26	R/W	TXFUFIE	0x0	Enable the TXFUFIP interrupt.
D25	R/W	TXFSRIP	0x0	Enable the TXFSRIP interrupt.
D24	R/W	TXNCRIP	0x0	Enable the NCIP interrupt.

Bit(s)	Access	Mnemonic	Reset	Description
D23	R/W	TXECIE	0x0	Enable the ECIP interrupt.
D22	R/W	TXNRIE	0x0	Enable the NRIP interrupt.
D21	R/W	TXCAIE	0x0	Enable the CAIP interrupt.
D20	N/A	Reserved	N/A	N/A
D19	R	WSTAT	0x0	Debug field, indicating the W bit is set in the current buffer descriptor.
D18	R	ISTAT	0x0	Debug field, indicating the I bit is set in the current buffer descriptor.
D17	R	LSTAT	0x0	Debug field, indicating the L bit is set in the current buffer descriptor.
D16	R	FSTAT	0x0	Debug field, indicating the F bit is set in the current buffer descriptor.
D15:00	R	BLENSTAT	0x0	Debug field, indicating the current byte count.

## **[Module] Direct Mode TX Data FIFO**

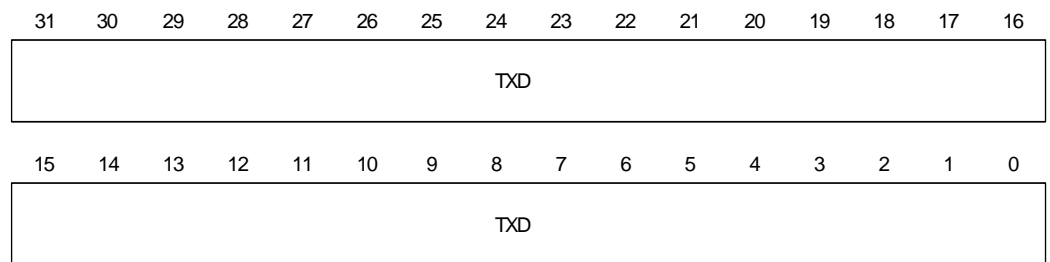

### **Addresses:**

FIM 0 9000_0028	FIM 1 9000_8028
UART A 9001_0028	UART B 9001_8028
UART C 9002_0028	UART D 9002_8028*
SPI 9003_0028	ADC 9003_8028*

\*UART D and ADC use different addresses but access the same shared DMA/FIFO.

The Direct Mode TX Data FIFO register is used when in direct mode of operation, to write the TX data FIFO. The write can be 8-, 16-, or 32-bit.

### **Register**

Register bit assignment

Bit(s)	Access	Mnemonic	Reset	Description
D31:00	W	TXD	0x0	TX Data FIFO Write register

[Module] Direct Mode TX Data Last FIFO

Addresses:

FIM 0 9000_002C	FIM 1 9000_802C
UART A 9001_002C	UART B 9001_802C
UART C 9002_002C	UART D 9002_802C*
SPI 9003_002C	ADC 9003_802C*

\*UART D and ADC use different addresses but access the same shared DMA/FIFO.  
The Direct Mode TX Data LAST FIFO register is used when in direct mode of operation, to write to the TX data FIFO and to cause a last status flag to be set for use by the peripheral. The write can be 8-, 16-, or 32-bit.

Register

Register bit assignment

Bit(s)	Access	Mnemonic	Reset	Description
D31:00	W	TXDL	0x0	TX Data with Last Status FIFO Write register.

## I/O HUB MODULE

*[Module] Direct Mode TX Data Last FIFO*

# Serial Control Module: UART

## C H A P T E R 1 0

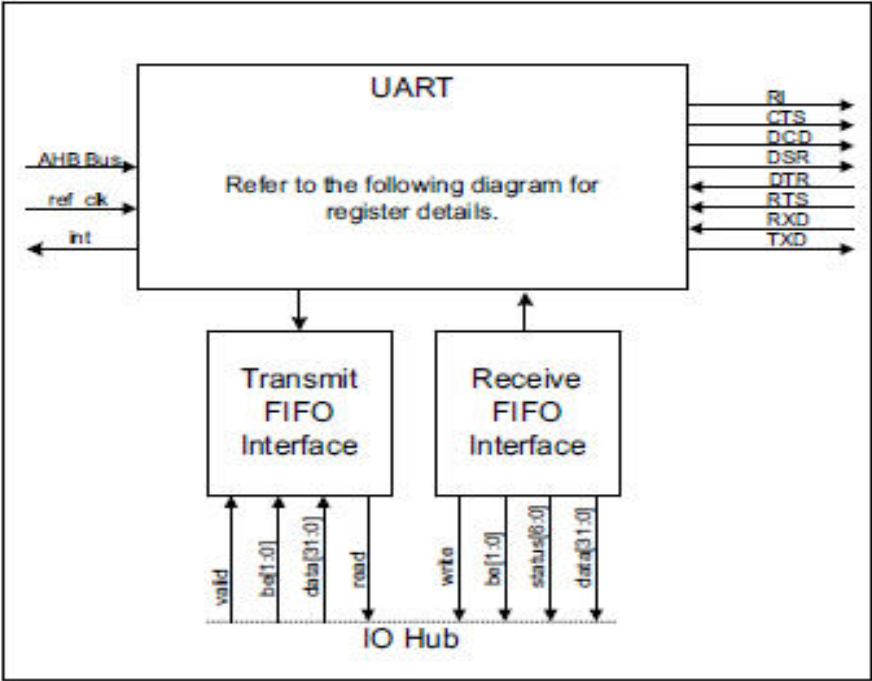

The processor ASIC supports four independent universal asynchronous receiver/transmitter (UART) channels (A through D). Each channel supports several modes, conditions, and formats.

### Features

- 4 UARTs
- DMA transfers to and from system memory
- Independent receive and transmit programmable bit-rate generators
- High speed data transfer up to 1.8432 Mbps
  - Programmable data format
    - 5 to 8 data bits
    - Odd, even, or no parity
    - 1 or 2 stop bits
    - MSB or LSB first
- Programmable channel modes
  - Normal
  - Local loopback
  - Remote loopback
- Modem control signal support
  - RTS, CTS, DTR, DSR, DCD, RI
- Maskable interrupt conditions
  - Receiver idle
  - Transmitter idle
  - Receive error conditions
  - Character gap timeout
  - Character match events
  - CTS, DSR, DCD, RI state change detection
- RS485 transceiver control signal
- Transmit FIFO bypass to force out a character
- HDLC available on UART C. See “Serial Control Module: HDLC” on page 421 for details.

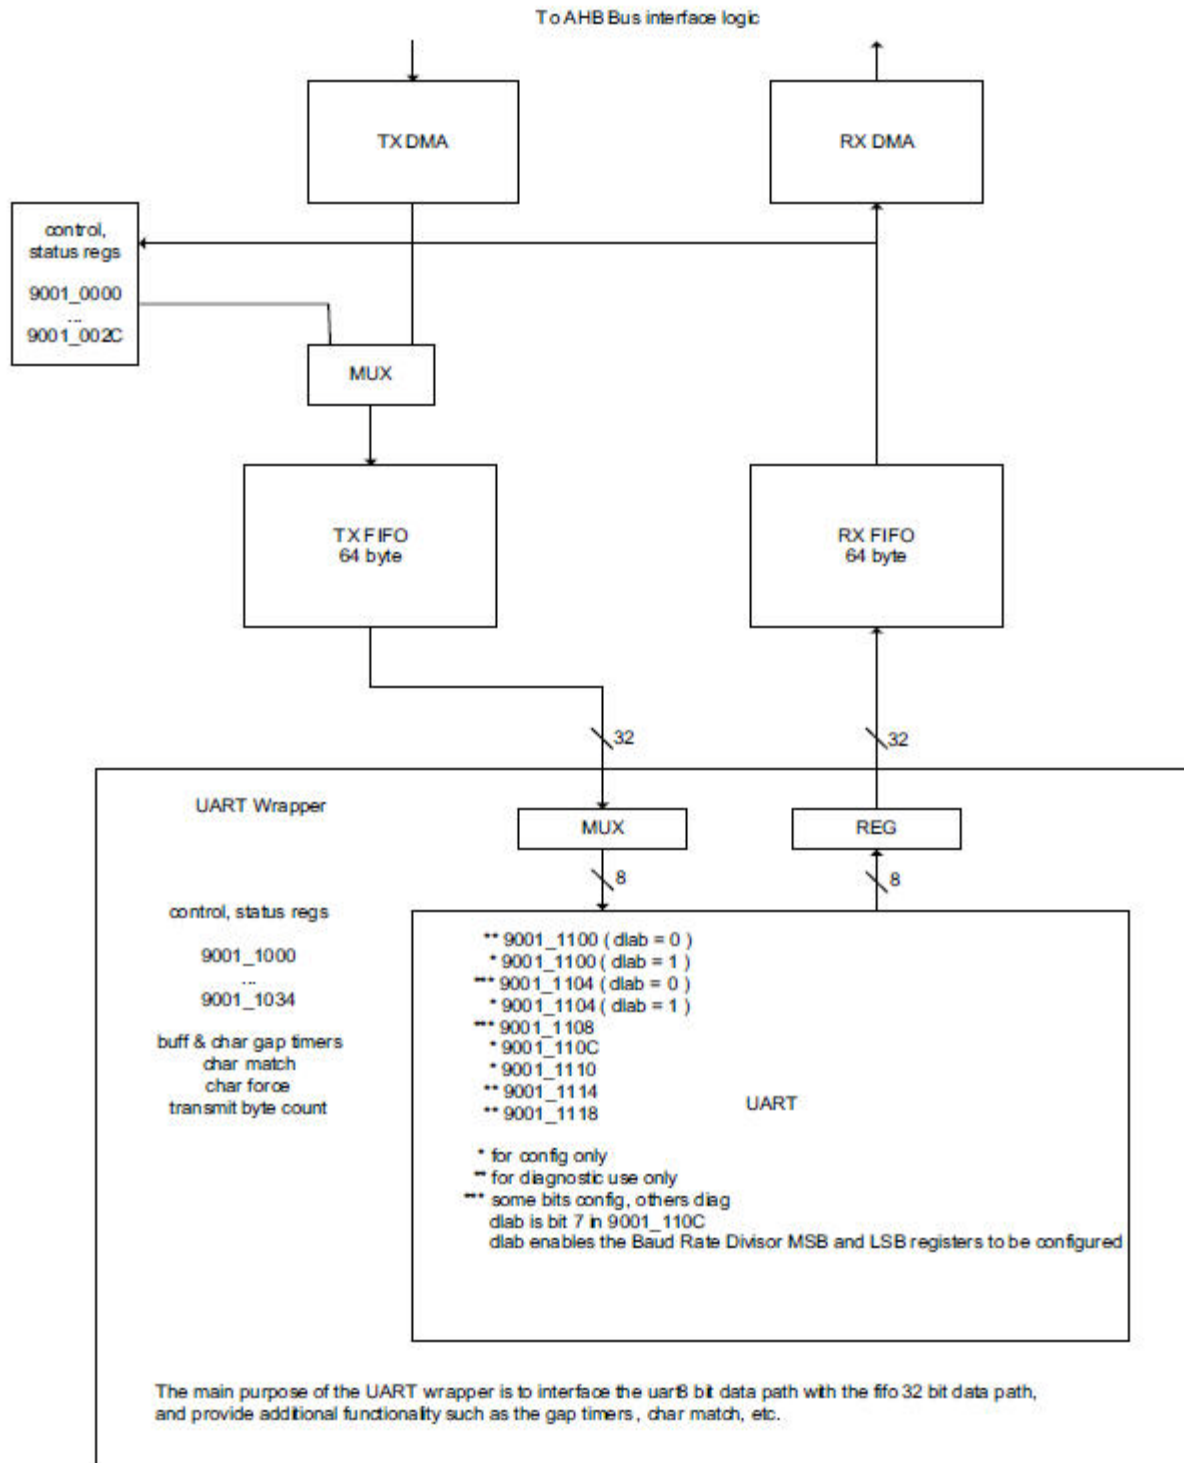

UART module structure

IO HUB and UART A data path and register addresses are shown below.

## Example register configuration

The UART achieves normal mode operation by programming the UART and Wrapper configuration registers.

### Example configuration

This example shows a normal mode operation configuration for a hyperterminal application. Any field not specified in this table can be left at reset value.

Control register	Field	Value	Comment
UART Line Control register (0x10c)	DLAB	0x1	Enables access to baud rate registers
UART Baud Rate Divisor LSB (0x100)	BRDL	0xC0	Set baud rate to 9600 bps MSB defaults to 0x0
UART Line Control register (0x10c)	DLAB	0x0	Disables access to baud rate registers
	WLS	0x3	8 bits per character
UART FIFO Control register (0x108)	FIFOEN	0x01	Enable RX and TX FIFOs
UART Interrupt Enable register (0x104)	ETBEI	0x1	Enable the Transmitter Holding Register Empty Interrupt. enables the Wrapper to write a transmit character to the UART.
Wrapper Configuration register	TX FLOW [4]Software	0x1	TX Enabled
	RXEN	0x1	Enable Wrapper receive function
	TXEN	0x1	Enable Wrapper transmit function

## Baud rate generator

The baud rate clock is generated by dividing the system reference clock by a programmable divisor; use this formula:

$$BR = CLK_{ref} / (BRD \times 16)$$

$$BRD = (CLK_{ref} / BR) \times 16$$

Where:

BR = Baud Rate clock

$CLK_{ref}$  = Clock reference

BRD = Baud Rate Divisor (registers Baud rate divisor MSB, LSB)

The default reference clock for the UARTs is the system reference clock input on pin x1\_sys\_osc. The UART reference clock ( $CLK_{ref}$ ) optionally can be input on GPIO\_A[3].

Note: This pin is also used for configuration at power-up.

### Baud rates

This table shows the baud rates achieved with  $CLK_{ref}$  set to 29.4912 MHz:

Divisor	Baud rate
1	1,843,200
2	921,600
4	460,800
8	230,400
16	115,200
32	57,600
48	38,400
64	28,800
96	19,200
128	14,400
192	9,600
384	4,800
768	2,400

## Hardware-based flow control

The UART module provides expanded functionality for hardware-based flow control. The RTS signal normally indicates the state of the receive FIFO. The CTS signal

normally halts the transmitter. With this UART module, the RI, CTS, DCD, or DSR signals can halt the transmitter. Program these features using the TXFLOW bits in the Wrapper Configuration register. See “Wrapper Control and Status registers” on page 394.

## Character-based flow control (XON/XOFF)

Traditional character-based software flow control requires the processor to match the flow control characters and control the transmitter accordingly. The traditional characters, XOFF(0x13) and XON (0x11) may be used, or any other characters that would not occur in the normal data stream. This UART module performs the character matching function in hardware and automatically updates the state of the transmitter, which allows character-based flow control to achieve nearly the same response time as hardware-based flow control.

### Example configuration

Configure the character-based flow control using at least two Receive Character Match registers and the Receive Character-Based Flow Control register. This table shows a sample configuration for a system transferring 8 data bits per character.

Note: The enable bit in the character match control registers need not be set.

Control register	Field	Value	Comment
Receive Character Match Control Register 0	ENABLE	1	Enable character match
	MASK	0x00	Mask bits
	DATA	0x7e	Define character
Receive Character Match Control Register 1	ENABLE	1	Enable character match
	MASK	0x00	Mask bits
	DATA	0x81	Define character
Receive Character-Based Flow Control register	FLOW0	0x2	XON when matched
	FLOW1	0x3	XOFF when matched

## Forced character transmission

The UART provides a mechanism in which you can bypass data in the transmit FIFO with a specific character. The specified character is transmitted after the current character completes, regardless of any flow control mechanism that might stall normal data transmission.

Use the Force Transmit Character Control register to program this operation.

### Force character transmission procedure

These steps outline a single force character transmission operation:

- 1 Read the Force Transmit Character Control register and verify that the ENABLE field is 0. The Force Transmit Character Control register must not be written while the ENABLE field is 1.
- 2 Write the required character either prior to, or with writing a one to the ENABLE bit.

### Collecting feedback

Force character transmission completion status is available. It is up to you as to whether you want to collect feedback. If you do want to collect feedback, these are your options:

- Poll the ENABLE field in the Force Transmit Character Control register until it reads 0.
- Poll the FORCE field in the Interrupt Status register until it reads 1.
- Enable the FORCE interrupt by writing a 1 to the FORCE field in the Interrupt Enable register and service the interrupt when it occurs.

## ARM wakeup on character recognition

The UART module provides a signal to the SCM module that can wake up the ARM processor. This signal is asserted when a specified character is received. Use the Receive Character Match Control registers and the ARM Wakeup Control register to implement the logic.

### Example configuration

This table shows a sample configuration where the wakeup signal is asserted on reception of any character:

Control register	Field	Value	Comment
Receive Character Match Control Register 0	ENABLE	1	Enable character match
	MASK	0xff	Mask all bits
	DATA	0x00	Don't care
ARM Wakeup Control register	ENABLE	1	Enable the function

## Wrapper Control and Status registers

The configuration registers for UART module A start at 0x9001\_1000, UART module B start at 0x9001\_9000, UART module C start at 0x9002\_1000, and UART module D start at 9002\_9000.

### Register address map

These are the configuration registers for UART module A. The configuration registers for other UART modules B, C, and D are the same, except they have different starting (base) addresses.

A = 0x 9001\_1000

B = 0x 9001\_9000

C = 0x 9002\_1000

D = 0x 9002\_9000

Address	Register
9001_1000	Wrapper Configuration
9001_1004	Interrupt Enable
9001_1008	Interrupt Status
9001_100C	Receive Character GAP Control
9001_1010	Receive Buffer GAP Control
9001_1014	Receive Character Match Control 0
9001_1018	Receive Character Match Control 1
9001_101C	Receive Character Match Control 2
9001_1020	Receive Character Match Control 3
9001_1024	Receive Character Match Control 4

## Wrapper Configuration register

Address: 9001\_1000 / 9001\_9000 / 9002\_1000 / 9002\_9000

This is the primary Wrapper Configuration register.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved	RXEN	TXEN	MODE	Reserved								RTSEN	DTREN	RXFLUSH	TXFLUSH
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RXBYTES		RXCLOCK	Reserved	TXFLOW						RL	RTS	RS485OFF		RS485ON	

### Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31	N/A	Reserved	N/A	N/A
D30	R/W	RXEN	0	0 Disable wrapper function 1 Enable wrapper to process receive characters
D29	R/W	TXEN	0	0 Disable transmitter function 1 Enable wrapper to process transmit characters
D28	R/W	MODE	0	Selects either UART or HDLC mode. This bit applies only to UART C. 0 UART mode 1 HDLC mode (see HDLC chapter)
D27:20	N/A	Reserved	N/A	N/A

Bits	Access	Mnemonic	Reset	Description
D19	R/W	RTSEN	0	Indicates which signal is output: RTS or RS485 transceiver control. 0    RTS 1    RS485 transceiver control
D18	R/W	DTREN	0	Indicates which signal is output: DTR or TX baud clock. 0    DTR 1    TX baud clock
D17	R/W	RXFLUSH	0	Resets the 64-byte RX FIFO to empty. Write a 1, then a 0 to reset the FIFO.
D16	R/W	TXFLUSH	N/A	Resets the 64-byte TX FIFO to empty. Write a 1, then a 0 to reset the FIFO.
D15:14	R	RXBYTES	00	Indicates how many bytes are pending in the wrapper. The wrapper writes to the RX FIFO only when 4 bytes are received or a buffer close event occurs, such as a character gap timeout, character match, or error.
D13	R/W	RXCLOSE	0	Allows software to close a receive buffer. Hardware clears this bit when the buffer has been closed. 0    Idle or buffer already closed 1    Software initiated buffer close
D12	N/A	Reserved	N/A	N/A
D11:06	R/W	TXFLOW	010000	Selects which signals are routed to the UART for hardware flow control. Transmit data is halted when the selected signal is deasserted. <b>[0]   CTS</b> 0    CTS disabled 1    CTS enabled <b>[1]   DCD</b> 0    DCD disabled 1    DCD enabled <b>[2]   DSR</b> 0    DSR disabled 1    DSR enabled <b>[3]   RI</b> 0    RI disabled 1    RI enabled <b>[4]   Software</b> 0    TX disabled 1    TX enabled <b>[5]   Receive character-based flow control</b> 0    Disabled 1    Enabled

Bits	Access	Mnemonic	Reset	Description
D05	R/W	RL	0	<b>Remote loopback</b> Provides an internal remote loopback feature. When the RL field is set to 1, the receive serial data signal is connected to the transmit serial data signal. A local loopback is provided in the UART.
D04	R/W	RTS	0	<b>RTS control</b> 0 Controlled directly by UART 1 Deasserted when RX FIFO is half full
D03:02	R/W	RS485OFF	00	<b>RS485 transceiver deassertion control</b> In bit times after the stop bit period 00 0 01 1 10 1.5 11 2
D01:00	R/W	RS485ON	00	<b>RS485 transceiver assertion control</b> In bit times before the falling edge of the start bit 00 0 01 1 10 1.5 11 2

## Interrupt Enable register

Address: 9001\_1004 / 9001\_9004 / 9002\_1004 / 9002\_9004

Use the Interrupt Enable register to enable interrupt generation on specific events.  
Enable the interrupt by writing a 1 to the appropriate bit field(s).

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:22	R/W	Not used	0	Write this field to 0.
D21	R/W	Reserved	0	Always write to 0.
D20	R/W	FORCE	0	<b>Enable force complete</b> Enables interrupt generation when a force character transmission operation has completed.
D19	R/W	OFLOW	0	<b>Enable overflow error</b> Enables interrupt generation if the 4-character FIFO in the UART overflows.  Note: This should not happen in a properly configured system.
D18	R/W	PARITY	0	<b>Enable parity error</b> Enables interrupt generation when a character is received with a parity error.
D17	R/W	FRAME	0	<b>Enable frame error</b> Enables interrupt generation when a character is received with a framing error.
D16	R/W	BREAK	0	<b>Enable line break</b> Enables interrupt generation when a line break condition occurs.
D15	R/W	BGAP	0	<b>Enable buffer gap</b> Enables interrupt generation when a buffer gap timeout event occurs.
D14	R/W	RXCLS	0	<b>Software receive close</b> Enables interrupt generation when software forces a buffer close.
D13	R/W	CGAP	0	<b>Enable character gap</b> Enables interrupt generation when a character gap timeout event occurs.
D12	R/W	MATCH4	0	<b>Enable character match4</b> Enables interrupt generation when a receive character match occurs against the Receive Match Register 4.
D11	R/W	MATCH3	0	<b>Enable character match3</b> Enables interrupt generation when a receive character match occurs against the Receive Match Register 3.
D10	R/W	MATCH2	0	<b>Enable character match2</b> Enables interrupt generation when a receive character match occurs against the Receive Match Register 2.
D09	R/W	MATCH1	0	<b>Enable character match1</b> Enables interrupt generation when a receive character match occurs against the Receive Match Register 1.

Bits	Access	Mnemonic	Reset	Description
D08	R/W	MATCH0	0	<b>Enable character match0</b> Enables interrupt generation when a receive character match occurs against the Receive Match Register 0.
D07	R/W	DSR	0	<b>Enable data set ready</b> Enables interrupt generation whenever a state change occurs on input signal DSR.
D06	R/W	DCD	0	<b>Enable data carrier</b> Enables interrupt generation whenever a stat change occurs on input signal DCD.
D05	R/W	CTS	0	<b>Enable clear to send</b> Enables interrupt generation whenever a state change occurs on input signal CTS.
D04	R/W	RI	0	<b>Enable ring indicator</b> Enables interrupt generation whenever a state change occurs on input signal RI.
D03	R/W	TBC	0	<b>Enable transmit buffer close</b> Enables interrupt generation when the UART transmit FIFO indicates to the UART transmitter that a byte corresponds to a buffer close event.
D02	R/W	RBC	0	<b>Enable receive buffer close</b> Enables interrupt generation whenever a buffer close event is passed from the UART receiver to the receive FIFO. These are the UART receive buffer close events: <ol style="list-style-type: none"> <li>1 Receive character match</li> <li>2 Receive character gap timeout</li> <li>3 Receive line break</li> <li>4 Receive framing error</li> <li>5 Receive parity error</li> </ol>
D01	R/W	TX_IDLE	0	<b>Enable transmit idle</b> Enables interrupt generation whenever the transmitter moves from the active state to the idle state. This indicates that the transmit FIFO is empty and the transmitter is not actively shifting out data.
D00	R/W	RX_IDLE	0	<b>Enable receive idle</b> Enables interrupt generation whenever the receiver moves from the active state to the idle state. If a start bit is not received after a stop bit, the receiver enters the idle state.

## Interrupt Status register

Address: 9001\_1008 / 9001\_9008 / 9002\_1008 / 9002\_9008

The Interrupt Status register provides status about UART events. All events are indicated by reading a 1 and are cleared by writing a 1.

## Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:22	R/W	Not used	0	Write this field to 0.
D21	R/W1TC	Reserved	0	<b>UART interrupt</b> Indicates that the UART has generated an interrupt.
D20	R/W1TC	FORCE	0	<b>Force complete</b> Indicates that a force character transmission operation has completed.
D19	R/W1TC	OFLOW	0	<b>Enable overflow error</b> Indicates that an overflow occurred in the UART's 4-character FIFO. Note: This should not happen in a properly configured system.
D18	R/W1TC	PARITY	0	<b>Parity error</b> Indicates that at least one character has been received with a parity error.
D17	R/W1TC	FRAME	0	<b>Frame error</b> Indicates that at least one character has been received with a framing error.
D16	R/W1TC	BREAK	0	<b>Line break</b> Indicates that a line break condition has occurred.
D15	R/W1TC	BGAP	0	<b>Buffer gap</b> Indicates that a buffer gap timeout event has occurred.
D14	R/W1TC	RXCLS	0	<b>Software receive close</b> Indicates a software-initiated buffer close has completed.
D13	R/W1TC	CGAP	0	<b>Character gap</b> Indicates that a character gap timeout event has occurred.

Bits	Access	Mnemonic	Reset	Description
D12	R/W1TC	MATCH4	0	<b>Character match4</b> Indicates that a receive character match has occurred against the Receive Match Register 4.
D11	R/W1TC	MATCH3	0	<b>Character match3</b> Indicates that a receive character match has occurred against the Receive Match Register 3.
D10	R/W1TC	MATCH2	0	<b>Character match2</b> Indicates that a receive character match has occurred against the Receive Match Register 2.
D09	R/W1TC	MATCH1	0	<b>Character match1</b> Indicates that a receive character match has occurred against the Receive Match Register 1.
D08	R/W1TC	MATCH0	0	<b>Character match0</b> Indicates that a receive character match has occurred against the Receive Match register 0.
D07	R/W1TC	DSR	0	<b>Data set ready</b> Indicates that a state change has occurred on input signal DSR.
D06	R/W1TC	DCD	0	<b>Data carrier detect</b> Indicates that a state change has occurred in input signal DCD.
D05	R/W1TC	CTS	0	<b>Clear to send</b> Indicates that a state change has occurred on input signal CTS.
D04	R/W1TC	RI	0	<b>Ring indicator</b> Indicates that a state change has occurred on input signal RI.
D03	R/W1TC	TBC	0	<b>Transmit buffer close</b> Indicates that transmission of the last byte in a transmit buffer has completed.
D02	R/W1TC	RBC	0	<b>Receive buffer close</b> Indicates that a UART receive buffer close condition has occurred. These are UART receive buffer close events: <ol style="list-style-type: none"> <li>1 Receive character match</li> <li>2 Receive character gap timeout</li> <li>3 Receive line break</li> <li>4 Receive framing error</li> <li>5 Receive parity error</li> </ol>

Bits	Access	Mnemonic	Reset	Description
D01	R/W1TC	TX_IDLE	0	<b>Transmit idle</b> Indicates that the transmitter has moved from the active state to the idle state. The transmitter moves from the active state to the idle state when the transmit FIFO is empty and the transmitter is not actively shifting out data.
D00	R/W1TC	RX_IDLE	0	<b>Receive idle</b> Indicates that the receiver has moved from the active state to the idle state. The receiver moves from the active state to the idle state when a start bit has not been received after the previous stop bit.

## Receive Character GAP Control register

Address: 9001\_100C / 9001\_900C / 9002\_100C / 9002\_900C

The Receive Buffer GAP Timer is used to close the receive buffer when the buffer has been open longer than the timer is set to. When the timer is enabled, it begins counting down when a character is received. If a new character is received prior to the timer reaching zero, the timer is reset and begins counting again. The timer can be configured to provide an interval in the range of 0.07 uS to 1.137 S.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ENABLE	Not used							VALUE							
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
VALUE															

### Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31	R/W	ENABLE	0	<b>Enable receive character gap timer</b> Write a 1 to this field to enable the receive character gap timer.
D30:25	R/W	Not used	0x0	<b>Write this field to 0.</b>
D24:00	R/W	VALUE	0	<b>Value</b> Defines the period between receiving the stop bit and asserting the character gap timeout event. Use this equation to compute the required divisor value: $\text{Value} = ((\text{FCLK} * \text{gap\_period}) - 1)$ $\text{FCLK} = \text{Nominal } 29.4912 \text{ MHz}$ $\text{gap\_period} = \text{Desired character gap period}$ A reasonable setting is 10 bit periods one character plus the start and stop bits. Given a data rate of 115,200bps, the desired period is 86.8us and the timeout value is 2559 <sub>d</sub> .

## Receive Buffer GAP Control register

Address: 9001\_1010 / 9001\_9010 / 9002\_1010 / 9002\_9010

The Receive Buffer GAP Timer is used to close the receive buffer when the buffer has been open longer than the timer is set to. When the timer is enabled, it begins counting down when the first character is received in a new buffer. If the buffer is closed prior to the timer reaching zero, the timer is reset and waits for the start of another buffer to begin counting. The timer can be configured to provide an interval in the range of 0.07 uS to 1.137S.

## Register

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31	R/W	ENABLE	0x0	<b>Enable transmit bit rate generation</b> Write a 1 to enable the transmit bit rate generator.
D30:25	R/W	Not used	0x0	<b>Write this field to 0x0.</b>
D24:00	R/W	VALUE	0x0	<b>Value</b> Defines the period between receiving the stop bit and asserting the buffer gap timeout event. Use this equation to compute the required divisor value: $Value = ((FCLK * gap\_period) - 1)$ $F_{CLK} = \text{Nominal } 29.4912 \text{ Mhz}$ $gap\_period = \text{Desired buffer gap period}$ A reasonable setting is 64 character or 640 bit periods. Given a baud rate of 115,200 bps, the desired period is 5.55ms and the timeout value is 163,839 <sub>d</sub> .

## Receive Character Match Control register

Addresses:

	match 0	match 1	match 2	match 3	match 4
UART A	9001_1014	9001_1018	9001_101C	9001_1020	9001_1024
UART B	9001_9014	9001_9018	9001_901C	9001_9020	9001_9024

UART C	9002_1014	9002_1018	9002_101C	9002_1020	9002_1024
UART D	9002_9014	9002_9018	9002_901C	9002_9020	9002_9024

The Receive Character Match Control registers configure the receive character match control logic. Each UART module has five Receive Character Match Control registers. When a match occurs, the current buffer is closed, with the character that matched being the last character written into the buffer.

## Register

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31	R/W	ENABLE	0	<b>Enable character match</b> Write a 1 to enable the receive character match control logic.
D30:24	R	Not used	0x0	Write this field to 0.
D23:16	R/W	MASK	0x0	<b>Mask</b> Allows you to not include specific bits in the receive character match operation. Writing 1 masks off the bit in the specified position. Bit positions that are not used should always be masked. For example, bit positions 9 through 12 should always be masked for 8-bit characters.
D15:08	R	Not used	0x0	Write this field to 0.
D07:00	R/W	DATA	0x0	<b>Data</b> Allows you to specify the receive characters to match against.

## Receive Character-Based Flow Control register

Address: 9001\_1028 / 9001\_9028 / 9002\_1028 / 9002\_9028

The Receive Character-Based Flow Control register lets you define the UART module's receive character-based flow control operation. Use this register in

conjunction with the Receive Character Match Control registers to define the flow control characters. If enabled, this function's output is wired to the UART module instead of the CTS signal.

**Caution:** Be aware that if multiple matches occur, an XOFF assertion will supersede an XON assertion.

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31	R/W	ENABLE	0	<b>Force transmit enable</b> Use this field to force the transmitter to send the character specified in the CHAR field (D07:00). All user-specified rules, such as bit order, parity, or number of stop bits, are enforced. Write a 1 to enable this field. Hardware clears the field once the character has been transmitted. Writing a 1 to this field when it is already a 1 has unpredictable results. Note: Writing a 1 to this field also clears the FORCE field in the Interrupt Status register.
D30	R	BUSY	0	<b>Read-only busy</b> Reading a 1 indicates that the force operation you initiated is in progress.
D29:08	R	Not used	0	Write this field to 0.
D07:00	R/W	CHAR	0	<b>Force character</b> Defines the character that is forced out of the transmitter.

## ARM Wakeup Control register

Address: 9001\_1030 / 9001\_9030 / 9002\_1030 / 9002\_9030

Use the ARM Wakeup Control register to enable the ARM wakeup control logic. Refer to “ARM wakeup on character recognition” on page 393 for more information.

D03	R	DDCD	N/A	<b>Delta DCD indicator</b> Indicates that an edge was found on DCD since the last time the register was read.
D02	R	TERI	N/A	<b>Trailing edge of RI indicator</b> Indicates that RI has changed from a 0 to a 1.
D01	R	DDSR	N/A	<b>Delta DSR indicator</b> Indicates that an edge was found on DSR since the last time the register was read.
D00	R	DCTS	N/A	<b>Delta CTS indicator</b> Indicates that an edge was found on CTS since the last time the register was read.

# Serial Control Module: HDLC

## C H A P T E R 1 1

The HDLC module allows full-duplex synchronous communication. Both the receiver and transmitter can select either an internal or external clock. The HDLC module encapsulates data within opening and closing flags, and sixteen bits of CRC precedes the closing flag. All information between the opening and closing flag is *zero-stuffed*; that is, if five consecutive ones occur, independent of byte boundaries, a zero is automatically inserted by the transmitter and automatically deleted by the receiver. This allows a flag byte (07Eh) to be unique within a serial stream. The standard CRC-CCITT polynomial ( $x^{16} + x^{12} + x^5 + 1$ ) is implemented, with the generator and checker preset to all ones.

### HDLC module structure

### Receive and transmit operations

Both receive and transmit operations are essentially automatic.

**Receive operation**

In the receiver, each byte is marked with status to indicate end-of-frame, short frame, and CRC error. The receiver automatically synchronizes on flag bytes, and presets the CRC checker accordingly. If the current receive frame is not needed (for example, because it is addressed to a different station), a flag search command is available. The flag search command forces the receiver to ignore the incoming data stream until another flag is received.

**Transmit operation**

In the transmitter, the CRC generator is preset and the opening flag transmitted automatically after the first byte is written to the transmitter buffer. The CRC and the closing flag are transmitted after the byte that is written to the buffer through the Address register. If no CRC is required, writing the last byte of the frame to the Long Stop register automatically appends a closing flag after the last byte.

**Transmitter underflow**

If the transmitter underflows, either an abort or a flag is transmitted, under software control. There is a command available to send the abort pattern (seven consecutive ones) if a transmit frame needs to be aborted prematurely. The abort command takes effect on the next byte boundary and causes an FEh (a zero followed by seven ones) transmission, after which the transmitter sends the idle line condition. The abort command also purges the transmit FIFO. The idle line condition can be either flags or all ones.

**Clocking**

A 15-bit divider circuit provides the clocking for the HDLC module. This clock is sixteen times the data rate. The receiver uses a digital phase locked loop (DPLL) to generate a synchronized receive clock for the incoming data stream. The HDLC module also allows for an external 1x (same speed as the data rate) clock for both the receiver and the transmitter.

HDLC receive and transmit clocks can be input or output. When using an external clock, the maximum data rate is one-sixth of the 29.4912 MHz reference clock rate, or 4.9152 Mbps.

**Bits**

The transmitter cannot send an arbitrary number of bits, but only a multiple of bytes. The receiver, however, can receive frames of any bit length. If the last "byte" in the frame is not eight bits, the receiver sets a status flag that is buffered along with this last byte. Software then uses the table shown next to determine the number of valid data bits in this last "byte." Note that the receiver transfers all bits

between the opening and closing flags, except for the inserted zeroes, to the receiver data buffer.

### Last byte bit pattern table

Last byte bit pattern	Valid data
bbbbbbb0	7
bbbbbb01	6
bbbbbb011	5
bbbb0111	4
bbb01111	3
bb011111	2
b0111111	1

## Data encoding

The HDLC module provides several types of data encoding:

- Normal NRZ
- NRZI
- Biphase-Level (Manchester)
- Biphase-Space (FM0)
- Biphase-Mark (FM1)

### Encoding examples

This figure shows examples of the data encoding types.

- In NRZI, Biphase-Space and Biphase-Mark, the signal level does not convey information. The placement of the transitions determine the data.
- In Biphase-Level, the polarity of the transmission determines the data.

## Digital phase-locked-loop (DPLL) operation: Encoding

In the HDLC module, the internal clock comes from the output of the dedicated divider. The divider output is divided by 16 to form the transmit clock and is fed to the DPLL to form the receive clock. The DPLL basically is a divide-by-16 counter that uses the transition timings on the receive data stream to adjust its count. The DPLL adjusts the count so the DPLL output is placed properly in the bit cells to sample the receive data.

### Transitions

To work properly, the receive data stream requires transitions. NRZ data encoding does not guarantee transitions in all cases (for example, a long string of zeroes), but the other data encodings do. NRZI guarantees transitions because of inserted zeroes. The Biphase encodings all have at least one transition per bit cell.

### DPLL-tracked bit cell boundaries

The DPLL counter normally counts by 16 but if a transition occurs earlier or later than expected, the count is modified during the next count cycle.

- If the transition occurs earlier than expected, the bit cell boundaries are early with respect to the DPLL-tracked cell boundaries and the count is shortened by either one or two counts.
- If the transition occurs later than expected, the bit cell boundaries are late with respect to the DPLL-tracked bit cell boundaries and the count is lengthened by either one or two counts.

How far off the DPLL-tracked bit cell boundaries are determines whether the count is adjusted by one or two. This tracking allows for minor differences in the transmit and receive clock frequencies.

### NRZ and NRZI data encoding

With NRZ and NRZI data encoding, the DPLL counter runs continuously and adjusts after every receive data transition.

Because NRZ encoding does not guarantee a minimum density of transitions, the difference between the sending data rate and the DPLL output clock rate must be very small, and depends on the longest possible run of zeros in the received frame.

NRZI encoding guarantees at least one transition every six bits (with the inserted zeroes). Because the DPLL can adjust by two counts every bit cell, the maximum difference between the sending data rate and the DPLL output clock rate is 1/48 (~2%).

### Biphase data encoding

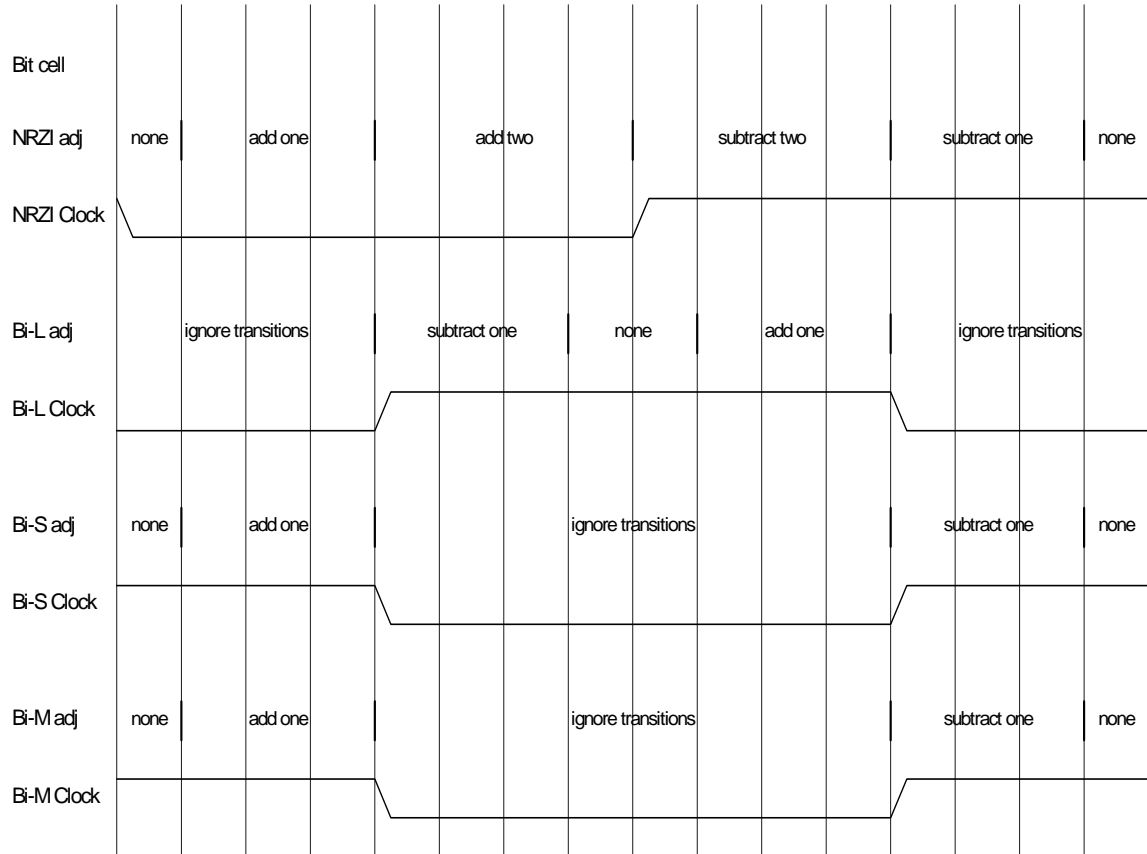

With biphase data encoding, the DPLL works in multiple-access conditions where there may not be flags on the idle line. The DPLL properly generates an output clock based on the first transition in the leading zero of an opening flag. Similarly, the DPLL requires only the completion of the closing flag to provide the extra two clocks to the receiver to properly assemble the data.

- In biphase-level mode, this means the transition that defines the last zero of the closing flag.
- In the biphase-mark and biphase-space modes, this means the transition that defines the end of the last zero of the closing flag.

## DPLL operation: Adjustment ranges and output clocks

This figure shows the adjustment ranges and output clock for the different DPLL modes of operation:

### NRZ and NRZI encoding

With NRZ and NRZI encoding, all transitions occur on bit-cell boundaries and the data should be sampled in the middle of the bit cell.

- If a transition occurs after the expected bit-cell boundary, but before the midpoint, the DPLL needs to lengthen the count to line up the bit-cell boundaries; this corresponds to the “add one” and “add two” regions of the figure.
- If a transition occurs before the bit-cell boundary, but after the midpoint, the DPLL needs to shorten the count to line up the bit-cell boundaries; this corresponds to the “subtract one” and “subtract two” regions shown in the figure.
- The DPLL makes no adjustment if the bit-cell boundaries are lined up within one count of the divide-by-sixteen counter. The regions that adjust the count by two allow the DPLL to synchronize faster to the data stream when starting up.

### Biphase-Level encoding

With biphase-level encoding, there is a guaranteed “clock” transition at the center of every bit-cell and optional “data” transitions at the bit-cell boundaries. The DPLL

only uses the clock transitions to track the bit-cell boundaries, by ignoring all transitions occurring outside a window around the center of the bit-cell. The window is half a bit-cell wide.

Because the clock transitions are guaranteed, the DPLL requires that they always be present. If no transition is found in the window around the center of the bit-cell for two successive bit-cells, the DPLL is not in lock and immediately enters search mode. Search mode presumes that the next transition seen is a clock transition and immediately synchronizes to this transition. No clock output is provided to the receiver during the search operation.

### Biphase-Mark and Biphase-Space encoding

Biphase-mark and biphase-space encoding are identical per the DPLL and are similar to biphase-level. The primary difference is the clock placement and data transitions. With these encodings, the clock transitions are at the bit-cell boundary and the data transitions are at the center of the bit-cell; the DPLL operation is adjusted accordingly. Decoding biphase-mark or biphase-space encoding requires that the data be sampled by both edges of the recovered receive clock.

### IRDA-compliant encode

There is an optional IRDA-compliant encode and decode function available. The encoder sends an active-high pulse for a zero and no pulse for a one. The pulse is 1/4th of a bit-cell wide. The decoder watches for active-low pulses which are stretched to one bit time wide to recreate the normal asynchronous waveform for the receiver. enabling the IRDA-compliant encode/decode modifies the transmitter so there are always two opening flags transmitted.

## Normal mode operation

The HDLC achieves normal mode operation by programming the HDLC and Wrapper configuration registers.

### Example configuration

This example shows a normal mode operation configuration for a typical application. Any field not specified in this table can be left at reset value.

Control register	Field	Value	Comment
HDLC Control register	CLK	0x3	Enable internal clock generation
HDLC Clock Divider High	EN	0x1	Enable the internal clock divider; the clock rate will be 1.8432 Mbps.

Control register	Field	Value	Comment
Wrapper Configuration register	RXEN	1	Enable Wrapper receive function
	TXEN	1	Enable Wrapper transmit function

## Wrapper and HDLC Control and Status registers

The configuration registers for the HDLC module are located at 0x9002\_9000.

### Register address map

These are the configuration registers located within a single HDLC module.

Address	Register
9002_9000	Wrapper Configuration
9002_9004	Interrupt Enable
9002_9008	Interrupt Status
9002_9100	HDLC Data Register 1
9002_9104	HDLC Data Register 2
9002_9108	HDLC Data Register 3
9002_910C	Reserved
9002_9110	HDLC Control Register 1
9002_9114	HDLC Control Register 2
9002_9118	HDLC Clock Divider Low
9002_911C	HDLC Clock Divider High

## Wrapper Configuration register

Address: 9002\_9000

This is the primary Wrapper Configuration register.

## Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31	N/A	Reserved	N/A	N/A
D30	R/W	RXEN	0	0 Disable wrapper function 1 Enable wrapper to process receive characters
D29	R/W	TXEN	0	0 Disable wrapper transmitter function 1 Enable wrapper to process transmit characters
D28	R/W	MODE	0	Applies only to UART channel C. 0 UART mode 1 HDLC mode
D27:18	N/A	Reserved	N/A	N/A
D17	R/W	RXFLUSH	0	Resets the contents of the 64-byte RXFIFO. Write a 1, then a 0 to reset the FIFO.
D16	R/W	TXFLUSH	0	Resets the contents of the 64-byte TX FIFO. Write a 1, then a 0 to reset the FIFO.
D15:14	R	RXBYTES	00	Indicates how many bytes are pending in the wrapper. The wrapper writes to the RX FIFO only when 4 bytes are received or a buffer close event occurs, such as end of frame.
D13	R/W	RXCLOSE	0	Allows software to close a receive buffer. Hardware clears this bit when the buffer has been closed. 0 Idle or buffer already closed 1 Software initiated buffer close
D12	R/W	CRC	0	Controls whether the HDLC transmitter hardware sends CRC bytes before the closing flag. 0 Send CRC bytes before the closing flag 1 Do not send CRC bytes before the closing flag; handled by software
D11:06	N/A	Reserved	0	N/A
D05	R/W	RL	0	<b>Remote loopback</b> Provides an internal remote loopback feature. When the RL field is set to 1, the receive HDLC data signal is connected to the transmit HDLC data signal.

Bits	Access	Mnemonic	Reset	Description
D04	R/W	LL	0	<b>Local loopback</b> Provides an internal local loopback feature. When the LL field is set to 1, the transmit HDLC data signal is connected to the receive HDLC data signal.
D03:00	N/A	Reserved	N/A	N/A

## Interrupt Enable register

Address: 9002\_9004

Use the Interrupt Enable register to enable interrupt generation on specific events. Enable the interrupt by writing a 1 to the appropriate bit field(s).

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Not used										HINT	Reserved	OFLOW	ICRC	VCRC	RABORT
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	RXCLS	Reserved										TBC	RBC	TX_IDLE	RX_IDLE

### Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:22	R/W	Not used	0	Write this field to 0.
D21	R/W	HINT	0	<b>Enable HDLC interrupt</b> Enables interrupt generation directly from the HDLC module. This is normally handled by hardware.
D20	N/A	Reserved	N/A	N/A
D19	R/W	OFLOW	0	<b>Enable overflow error</b> Enables interrupt generation if the 4-character FIFO in the HDLC overflows.  Note: This should not happen in a properly configured system.
D18	R/W	ICRC	0	<b>Enable invalid CRC</b> Enables interrupt generation when a frame is received with an invalid CRC.
D17	R/W	VCRC	0	<b>Enable valid CRC</b> Enables interrupt generation when a frame is received with a valid CRC.

Bits	Access	Mnemonic	Reset	Description
D16	R/W	RABORT	0	<b>Enable receive abort error</b> Enables interrupt generation when a frame is received with an abort.
D15	N/A	Reserved	N/A	N/A
D14	R/W	RXCLS	0	<b>Software receive close</b> Enables interrupt generation when software forces a buffer close.
D13:04	N/A	Reserved	N/A	N/A
D03	R/W	TBC	0	<b>Enable transmit buffer close</b> Enables interrupt generation when the HDLC transmit FIFO indicates to the HDLC transmitter that a byte corresponds to a buffer close event.
D02	R/W	RBC	0	<b>Enable receive buffer close</b> Enables interrupt generation whenever a buffer close event is passed from the HDLC receiver to the receive FIFO. These are the HDLC receive buffer close events: 1 Receive overrun detected 2 Receive abort detected 3 Buffer closed due to invalid CRC 4 Buffer closed due to valid CRC
D01	R/W	TX_IDLE	0	<b>Enable transmit idle</b> Enables interrupt generation whenever the transmitter moves from the active state to the idle state. This indicates that the transmit FIFO is empty and the transmitter is not actively shifting out data.
D00	R/W	RX_IDLE	0	<b>Enable receive idle</b> Enables interrupt generation whenever the receiver moves from the active state to the idle state. If a start bit is not received after a stop bit, the receiver enters the idle state.

## Interrupt Status register

Address: 9002\_9008

The Interrupt Status register provides status about HDLC events. All events are indicated by reading a 1 and are cleared by writing a 1.

## Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:22	R/W	Not used	0	Write this field to 0.
D21	R/W1TC	HINT	0	<b>HDLC interrupt</b> Indicates that the HDLC has generated an interrupt.
D20	N/A	Reserved	N/A	N/A
D19	R/W1TC	OFLOW	0	<b>Enable overflow error</b> Indicates that an overflow occurred in the HDLC's 4-byte FIFO.  Note: This should not happen in a properly configured system.
D18	R/W1TC	ICRC	0	<b>Invalid CRC</b> Indicates that a frame has been received with a CRC error.
D17	R/W1TC	VCRC	0	<b>Valid CRC</b> Indicates that a frame has been received with a valid CRC.
D16	R/W1TC	RABORT	0	<b>Receive abort error</b> Indicates that a frame has been received with an abort.
D15	N/A	Reserved	N/A	N/A
D14	R/W1TC	RXCLS	0	<b>Software receive close</b> Indicates a software-initiated buffer close has completed.
D13:04	N/A	Reserved	N/A	N/A
D03	R/W1TC	TBC	0	<b>Transmit buffer close</b> Indicates that transmission of the last byte in a transmit buffer has completed.
D02	R/W1TC	RBC	0	<b>Receive buffer close</b> Indicates that a HDLC receive buffer close condition has occurred. These are HDLC receive buffer close events: <ol style="list-style-type: none"> <li>1 Receive overrun detected</li> <li>2 Receive abort detected</li> <li>3 Buffer closed due to invalid CRC</li> <li>4 Buffer closed due to valid CRC</li> </ol>

Bits	Access	Mnemonic	Reset	Description
D01	R/W/TC	TX_IDLE	0	<b>Transmit idle</b> Indicates that the transmitter has moved from the active state to the idle state. The transmitter moves from the active state to the idle state when the transmit FIFO is empty and the transmitter is not actively shifting out data.
D00	R/W/TC	RX_IDLE	0	<b>Receive idle</b> Indicates that the receiver has moved from the active state to the idle state. The receiver moves from the active state to the idle state when a start bit has not been received after the previous stop bit.

## HDLC Data Register 1

Address: 9002\_9100

HDLC Data Register 1 reads data from the receive buffer and load data in the transmit buffer. This register is for debug purposes only.

### Register

### Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:08	N/A	Reserved	0	N/A
D07:00	R/W	HDATA	0	Read Returns the contents of the receive buffer Write Loads the transmit buffer with a byte of data

## HDLC Data Register 2

Address: 9002\_9104

HDLC Data Register 2 writes the last byte of data of a frame after which the CRC and closing flag are transmitted. This register is for debug purposes only.

## Register

## Register bit assignment

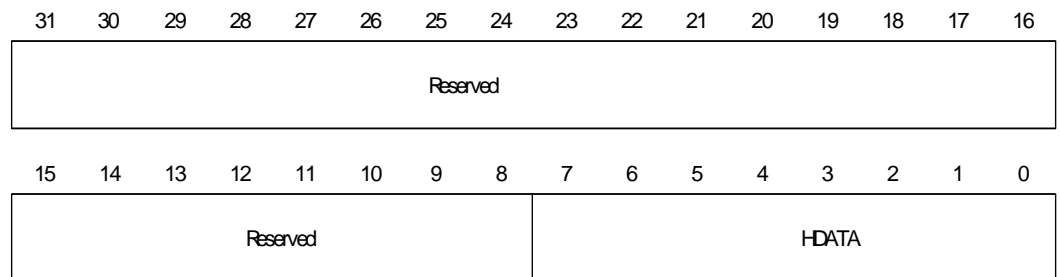

Bits	Access	Mnemonic	Reset	Description
D31:08	R	Not used	0	Write this field to 0.
D07:05	R/W	CMODE	0	<b>Coding mode</b> 000 NRZ data encoding for receiver and transmitter 010 RZI data encoding for receiver and transmitter 100 Biphas-Level (Manchester) data encoding for receiver and transmitter 110 Biphas-Space data encoding for receiver and transmitter 111 Biphas-Mark data encoding for receiver and transmitter
D04	R/W	HMODE	0	<b>HDLC mode</b> 0 Normal HDLC data encoding 1 Enable NRZI coding (1/4 bit-cell IRDA-compliant). This mode can be used only with internal clock and NRZ data encoding.
D03	R/W	IMODE	0	<b>Transmit idle mode</b> 0 Transmit flags while in idle mode 1 Transmit all 1s while in idle mode
D02	R/W	UMODE	0	<b>Underrun mode</b> 0 Transmit flag on underrun 1 Transmit abort on underrun
D01	R/W	ECLK	0	<b>External clock mode</b> 0 The HDLC module will use separate external receive and transmit clocks 1 The HDLC receiver and transmitter will both use the external transmit clock.
D00	R	Not used	0	Always write 0 to this bit.

## HDLC Clock Divider Low

.....

Address: 9002\_9118

Use the HDLC CLock Divider Low register to set bits 07:00 of the clock divider. This is the equation for the HDLC clock rate:

$$\text{HDLC rate (bps)} = \frac{29.4912 \text{ MHz}}{16 \times (\text{DIV} = 1)}$$

## Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Not used															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Not used								DIVL							

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:08	R	Not used	0	Write this field to 0.
D07:00	R/W	DIVL	0	Eight LSBs of the divider that generates the HDLC transmit and receive clock.

## HDLC Clock Divider High

Address: 9002\_911C

Use the HDLC CLock Divider High register to set bits 14:08 of the clock divider.

## Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Not used								EN	DIVH						

Register bit  
assignment

Bits	Access	Mnemonic	Reset	Description
D31:08	R	Not used	0	Write this field to 0.
D07	R/W	EN	0	<b>Clock enable</b> Must be set when the internal clock is used.
D06:00	R/W	DIVH	0	Seven MSBs of the divider that generates the HDLC transmit and receive clock.

# *Serial Control Module: SPI*

## C H A P T E R 1 2

**T**he processor ASIC contains a single high speed, four-wire, serial peripheral interface (SPI) module.

### Features

- DMA transfers to and from system memory
- Four-wire interface (RXD, TXD, CLK, CS)
- Multi-drop supported through GPIO programming
- Master or slave operation
- High speed data transfer
  - Master: 33.33 Mbps
  - Slave: 7.50 Mbps
- Programmable MSB/LSB formatting
- Programmable SPI mode (0, 1, 2, or 3)
- Master mode internal diagnostic loopback
- Maskable interrupt conditions
  - Receiver idle
  - Transmitter idle

## SPI module structure

## SPI controller

The SPI controller provides a full-duplex, synchronous, character-oriented data channel between master and slave devices, using a four-wire interface (RXD, TXD, CLK, CS#). The master interface operates in a broadcast mode. The slave interface is activated using the CS# signal. You can configure the master interface to address various slave interfaces using the GPIO pins.

### Simple parallel/serial data conversion

SPI provides simple parallel/serial data conversion to stream serial data between memory and a peripheral. The SPI port has no protocol associated with it other than transferring information in multiples of 8 bits.

### Full duplex operation

The SPI port can operate in full-duplex mode. Information transfer is controlled by a single clock signal. The clock and chip select signals are chip outputs for a master mode operation and inputs for a slave mode operation.

## SPI clocking modes

There are four SPI clocking modes. Each mode's characteristics are defined by the idle value of the clock, which clock edge captures data, and which clock edge drives data. The MODE field in the SPI Configuration register specifies the timing mode.

### Timing modes

SPI mode	SPI CLK Idle	SPI DATA IN capture edge	SPI DATA OUT drive edge
0	Low	Rising	Falling
1	High	Falling	Rising
2	Low	Falling	Rising
3	High	Rising	Falling

### Clocking mode diagrams

The next two diagrams show the four SPI clocking modes. SPI Mode0 and SPI Mode3 are the most commonly used modes.

#### SPI Mode0 and Mode3 functional timing

#### SPI Mode1 and Mode2 functional timing

## SPI clock generation

The reference clock for the SPI module is the system PLL output. This clock is a nominal 300 MHz.

- In SPI master mode, the clock is divided down to produce the required data rate.
- In SPI slave mode, the divided down clock recovers the input SPI clock.

### Clock generation samples

SPI clock generation is specified using the Clock Generation register. These are some examples of clock generation:

Interface Type	Data rate	DIVISOR
Master	33 Mbps	0x009
Master	20 Mbps	0x00F
Master	5 Mbps	0x03C
Master	500 Kbps	0x258
Slave	all	0x006

### In SPI master mode

In SPI master mode, the value programmed in the DIVISOR field must always be rounded up to the next whole integer. For example, if the required data rate is 14 Mbps, the calculation is  $(300 / 14)$  or 21.43.

- The value programmed in the DIVISOR field would be 0x016.
- The actual data rate would be 13.64 Mbps.
- The general equation is:

$$\text{DIVISOR} = \text{round Up} (\text{PLL output} / \text{interface data rate})$$

### In SPI slave mode

In SPI slave mode, the value programmed in the DIVISOR field should always be 0x006. The SPI slave mode data rate is determined by the frequency of the input clock provided by the external SPI master.

## System boot-over-SPI operation

The NET+SPI ASIC boots from an external, non-volatile, serial memory device. The device can be either a serial EEPROM or a serial Flash. In either case, the device must support a four-wire, mode0-compatible SPI interface.

The boot-over-SPI hardware interfaces to devices requiring an 8-bit address, 16-bit address, or 24-bit address. The address width is indicated by strapping pins `boot_mode[1:0]`.

## Available strapping options

boot_mode[1:0]	Address width
00	Disabled
01	8-bit address
10	24-bit address
11	16-bit address

## EEPROM/FLASH header

The boot-over-SPI hardware requires several pieces of user-supplied information to complete the boot operation. This information must be located in a 128-byte header starting at address zero in the external memory device. Each entry in the header is four bytes long.

## Header format

This is the format of the 128-byte header.

Entry	Name	Description
0x0	Size[19:0] (31:20 reserved)	Total number of words to fetch from the SPI-EEPROM. The total must include the 32-word header: (Code image size in bytes + 128) / 4)
0x4	Mode[27:0] (31:28 reserved)	All SDRAM components contain a Mode register. This register contains control information required to successfully access the component. The fields (available in any SDRAM specification) are defined as follows: <ul style="list-style-type: none"> <li>▪Burst length: 4 for 32-bit data bus, 8 for 16-bit data bus</li> <li>▪Burst type: Sequential</li> <li>▪CAS latency: Component-specific; 2 or 3</li> <li>▪OpMode: Standard</li> <li>▪Write burst mode: Programmed burst length</li> </ul> This value must be left-shifted such that it is aligned to the row address bits as specified in “Address mapping,” beginning on page 229. For example, 4Mx16 components can be combined to create a 32-bit bus. These parts require 12 row address bits. With a CAS2 access, the Mode register contents would be 0x22. This value is shifted 12 places to the left (0x00022000) to form the value in the SDRAM config field.
0x8	Divisor[9:0] (31:10 reserved)	Defines the interface data rate for the boot-over-SPI operation after the initial 16-bytes. A data rate of about 375 Kbps fetches the 16-byte header. See the Clock Generation register for more details.
0xc	HS Read[0] (31:1 reserved)	A 1 indicates the external device supports high-speed read operation. Serial FLASH devices operating above 20MHz generally support this feature.
0x10	Config register	See the Memory Controller chapter.

Entry	Name	Description
0x14	DynamicRefresh	See the Memory Controller chapter. For example, the value of this entry is 0x00000025 given a 74.9 MHz AHB clock and a 7.8125s refresh period.
0x18	DynamicReadConfig	See the Memory Controller chapter.
0x1c	DynamictRP	See the Memory Controller chapter
0x20	DynamictRAS	See the Memory Controller chapter
0x24	DynamictSREX	See the Memory Controller chapter
0x28	DynamictAPR	See the Memory Controller chapter
0x2c	DynamictDAL	See the Memory Controller chapter
0x30	DynamictWR	See the Memory Controller chapter
0x34	DynamictRC	See the Memory Controller chapter
0x38	DynamictRFC	See the Memory Controller chapter
0x3c	DynamictXSrt	See the Memory Controller chapter
0x40	DynamictRRD	See the Memory Controller chapter
0x44	DynamictMRD	See the Memory Controller chapter
0x48	DynamictConfig0	See the Memory Controller chapter. Field B (buffer enable, in the DynamicConfig0 register) should be set to 0 (buffers disabled). The buffers will be enabled by hardware as part of the boot process.
0x4c	DynamictRasCas0	See the Memory Controller Chapter
0x50- 0x7c	Reserved	
0x80	Boot Code	First 4 bytes of boot code

### Time to completion

The boot-over-SPI operation is performed in two steps.

- In the first step, the hardware fetches the 16-byte header. The data rate for this step is about 375 Kbps and completes in less than 0.5ms.
- In the second step, the hardware fetches the image at the user-specified data rate. Calculate time to completion for this step as shown:

$$\text{Time(s)} = (1 / \text{data\_rate}) * \text{IMAGE}_{\text{SIZE}}$$

For example, with a 20 Mbps data rate and a 256 KB (2Mb) image, the time to completion is approximately 105ms.

## SPI Control and Status registers

The configuration registers for the SPI module are located at 0x9003\_1000.

### Register address map

Address	Register
9003_1000	SPI Configuration register
9003_1010	Clock Generation register
9003_1020	Interrupt Enable register
9003_1024	Interrupt Status register

## SPI Configuration register

Address: 9003\_1000

This is the primary SPI Configuration register.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Not used															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Not used			MLB	DISCARD				Not used		MODE	RX BYTE	BT ORDER	SLAVE	MASTER	

### Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:13	R/W	Not used	0	Write this field to 0.
D12	R/W	MLB	0	<b>Enable master loopback mode</b> Write a 1 to enable the master mode transmitter to receiver loopback function.

Bits	Access	Mnemonic	Reset	Description
D11:08	R/W	DISCARD	0	<b>Discard bytes</b> Defines the number of bytes the receiver should drop when the transmitter has initiated a new operation. <ul style="list-style-type: none"> <li>■ A new operation is defined by the chip select signal being asserted low.</li> <li>■ The programmed value defines the number of bytes to discard.</li> <li>■ The maximum number of receive bytes that can be discarded is 14.</li> </ul>
D07:06	R/W	Not used	0	Write this field to 0.
D05:04	R/W	MODE	0	<b>SPI mode</b> Defines the required interface timing as specified in “Timing modes” on page 441.
D03	R/W	RXBYTE	0	Controls how the SPI receiver handles receive data. <ul style="list-style-type: none"> <li>■ RXBYTE set to 0 — The receiver buffers 4 bytes before writing to the RX FIFO.</li> <li>■ Write a 1 to RXBYTE — The receiver writes to the RX FIFO each time a new byte is received.</li> </ul> This allows low latency handling of SPI receive data.
D02	R/W	BITORDR	0x0	<b>Bit ordering</b> Controls the order in which bits are transmitted and received in the serial shift register. <ul style="list-style-type: none"> <li>■ BITORDR set to 0 — Bits are processed LSB first, MSB last.</li> <li>■ BITORDR set to 1 — Bits are processed MSB first, LSB last.</li> </ul>
D01	R/W	SLAVE	0	<b>Slave enable</b> Set this field to 1 to enable the SPI module for slave operation. The SLAVE field must not be set until all SPI configuration fields have been defined. You can set either the MASTER field (D00) or the SLAVE field, but not both.
D00	R/W	MASTER	0	<b>Slave enable</b> Set this field to 1 to enable the SPI module for master operation. The MASTER field must not be set until all SPI configuration fields have been defined. You can set either the MASTER field or the SLAVE field (D01), but not both.

## Clock Generation register

Address: 9003\_1010

Use this register to define the data rate of the interface.

*This register must be programmed in three steps. Failure to follow these steps can result in unpredictable behavior of the SPI module.*

### Register programming steps

- 1 Set the ENABLE field to 0. The DIVISOR field must not be changed.
- 2 Set the DIVISOR field to the value you want.
- 3 Set the ENABLE field to 1. The DIVISOR field must not be changed.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Not used															ENABLE
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Not used						Divisor									

### Register bit assignment

Bit(s)	Access	Mnemonic	Reset	Divisor
D31:17	R/W	Not used	0	Write this field to 0.
D16	R/W	ENABLE	0	<b>Enable clock generation</b> Write a 1 to this field to enable the SPI module clock generation logic.
D15:10	R/W	Not used	0	Write this field to 0.
D09:00	R/W	DIVISOR	0	<b>Divisor</b> Allows you to specify the required data rate of the interface. The reference clock used is the system PLL output. This frequency is a nominal 300 MHz. <ul style="list-style-type: none"> <li>■ For SPI master operation — Set this field to a value no smaller than 0x009. This produces the maximum supported data rate of 33 Mbps.</li> <li>■ For SPI slave operation — Always set this field to 0x006.</li> </ul>

## Interrupt Enable register

Address: 9003\_1020

Use the Interrupt Enable register to enable interrupt generation on specific events. Enable the interrupt by writing a 1 to the appropriate bit field(s).

Register

Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:02	R/W	Not used	0	Write this field to 0.
D01	R/W	TX_IDLE	0	<b>Enable transmit idle</b> Enables interrupt generation whenever the transmitter moves from the active state to the idle state. <ul style="list-style-type: none"><li>■ In master mode, this indicates that the transmit FIFO is empty and that the transmitter is not actively shifting out data.</li><li>■ In slave mode, this indicates that the externally provided chip select has been deasserted.</li></ul>
D00	R/W	RX_IDLE	0	<b>Enable receive idle</b> Enables interrupt generation whenever the receiver moves from the active state to the idle state. In either master or slave mode, this indicates that the chip select signal has been deasserted.

Interrupt Status register

Address: 9003\_1024

The Interrupt Status register provides status about SPI events. All events are indicated by reading a 1 and are cleared by writing a 1.

## Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Not used															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Not used													TX_IDLE	RX_IDLE	

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:02	R/W	Not used	0	Write this field to 0.
D01	R/W1TC	TX_IDLE	0	<b>Transmit idle</b> Indicates that the transmitter has moved from the active state to the idle state. The transmitter moves from the active state to the idle state when the transmit FIFO is empty and the transmitter is not actively shifting out data.
D00	R/W1TC	RX_IDLE	0	<b>Receive idle</b> Indicates that the receiver has moved from the active state to the idle state. The receiver moves from the active state to the idle state when a start bit has not been received within 4 bit periods of the previous stop bit.

## SPI timing characteristics

These are the guaranteed timing parameters for all four SPI clocking modes.

## SPI master timing parameters

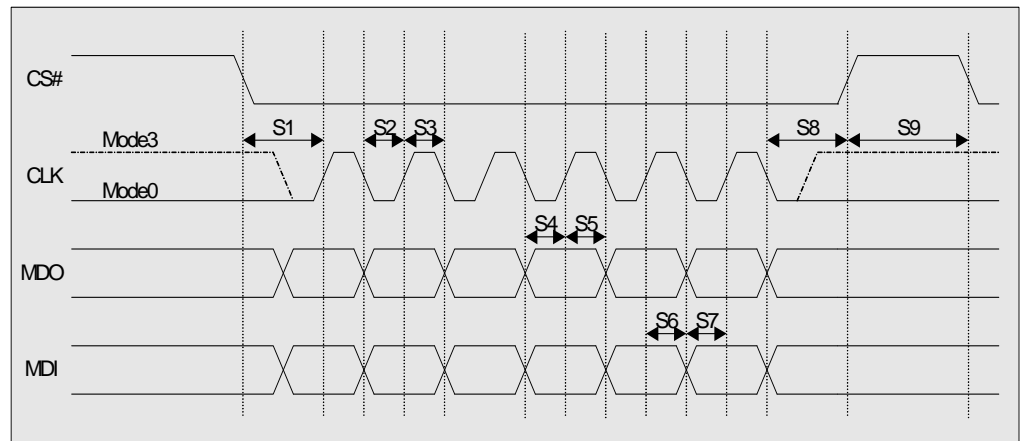

Parm	Description	Min	Max	Unit	Notes
S1	CS# falling to CLK rising	1		clock	1
S2	CLK period low time	12	13	ns	2
S3	CLK period high time	12	13	ns	2
S4	Data output setup to CLK rising	11		ns	3
S5	Data output hold from CLK rising	11		ns	3
S6	Data input setup to CLK rising	10		ns	4
S7	Data input hold from CLK rising	0		ns	4
S8	CLK falling to CS# rising	1		clock	1
S9	CS# deassertion time	4		clock	1

**Notes:**

- 1 The unit *clock* refers to the SPI master clock.
- 2 The SPI master interface clock duty cycle is always at least 52/48. The numbers shown here are for a 40 Mhz clock rate.
- 3 The numbers shown here are for a 40 Mhz clock rate. Usually, this parameter is one half the SPI master interface clock period less 1.5ns.
- 4 This parameter does not depend on the SPI master interface clock rate.

**SPI master timing diagram**

**SPI slave timing parameters**

Parm	Description	Min	Max	Unit	Notes
S11	CS# falling to CLK rising	50		ns	3
S12	CLK period low time	53	80	ns	1,2
S13	CLK period high time	53	80	ns	1,2
S14	Data input setup to CLK rising	10		ns	4
S15	Data input hold from CLK rising	15		ns	3
S16	Data output setup to CLK rising	80		ns	2
S17	Data output hold from CLK rising	67		ns	2
S18	CLK falling to CS# rising	50		ns	3
S19	CS# deassertion time	266		ns	2

**Notes:**

- 1 The SPI slave interface clock duty cycle should be no worse than 60/40.

- 2 The numbers shown here are for a 7.5 Mhz SPI slave interface clock rate.
- 3 The numbers shown here are for a 300 Mhz PLL output frequency. This value must be proportionally increased with a PLL output frequency decrease.
- 4 This parameter does not depend on any clock frequency.

### SPI slave timing diagram

# I2C Master/Slave Interface

## C H A P T E R 1 3

The I2C master/slave interface provides an interface between the ARM CPU and the I2C bus.

The I2C master/slave interface basically is a parallel-to-serial and serial-to-parallel converter. The parallel data received from the ARM CPU has to be converted to an appropriate serial form to be transmitted to an external component using the I2C bus. Similarly, the serial data received from the I2C bus has to be converted to an appropriate parallel form for the ARM CPU. The I2C master interface also manages the interface timing, data structure, and error handling.

### Overview

The I2C module is designed to be a master and slave. The slave is active only when the module is being addressed during an I2C bus transfer; the master can arbitrate for and access the I2C bus only when the bus is free (idle) — therefore, the master and slave are mutually exclusive.

### Physical I<sup>2</sup>C bus

The physical I<sup>2</sup>C bus consists of two open-drain signal lines: serial data (SDA) and serial clock (SCL). Pullup resistors are required; see the standard I<sup>2</sup>C bus specification for the correct value for the application. Each device connected to the bus is software-addressable by a unique 7- or 10-bit address, and a simple master/slave relationship exists at all times.

A master can operate as a master-transmitter (writes) or a master-receiver (reads). The slaves respond to the received commands accordingly:

- In transmit mode (slave is read), the host interface receives character-based parallel data from the ARM. The module converts the parallel data to serial format and transmits the serial data to the I<sup>2</sup>C bus.
- In receive mode (slave is written to), the I<sup>2</sup>C bus interface receives 8-bit-based serial data from the I<sup>2</sup>C bus. The module converts the serial data to parallel format and interrupts the host. The host's interrupt service routine reads the parallel data from the data register inside the I<sup>2</sup>C module. The serial data stream synchronization and throttling are done by modulating the

serial clock. Serial clock modulation can be controlled by both the transmitter and receiver, based in their hosts' service speed.

### Multi-master bus

The I<sup>2</sup>C is a true multi-master bus with collision detection and arbitration to prevent data corruption when two or more masters initiate transfer simultaneously. If a master loses arbitration during the addressing stage, it is possible that the winning master is trying to address the transfer. The losing master must therefore immediately switch over to its slave mode.

The on-chip filtering rejects spikes on the bus data line to preserve data integrity. The number of ICs that can be connected to the same bus is limited only by a maximum bus capacity of 400 pf.

## I<sup>2</sup>C external addresses

I<sup>2</sup>C external [bus] addresses are allocated as two groups of eight addresses (0000XXX and 1111XXX)

:

Slave address	R/W bit	Description
0000 000	0	General call address
0000 000	1	START byte (not supported in the processor)
0000 001	X	CBUS address (not supported in the processor)
0000 010	X	Reserved for different bus format
0000 011	X	Reserved
0000 1xx	X	hs-mode master code (not supported in the processor)
1111 1xx	X	Reserved
1111 0xx	X	10-bit slave address

The general call address is for addressing all devices connected to the I<sup>2</sup>C bus. A device can ignore this address by not issuing an acknowledgement. The meaning of the general call address is always specified in the second byte.

## I<sup>2</sup>C command interface

The I<sup>2</sup>C module converts parallel (8-bit) data to serial data and serial data to parallel data between the processor and the I<sup>2</sup>C bus, using a set of interface registers.

- The primary interface register for transmitting data is the CMD\_TX\_DATA\_REG (write-only).
- The primary interface register for receiving data is the STATUS\_RX\_DATA\_REG (read-only).

### Locked interrupt driven mode

I<sup>2</sup>C operates in a *locked interrupt driven mode*, which means that each command issued must wait for an interrupt response before the next command can be issued (illustrated in "Flow charts," beginning on page 463).

The first bit of the command — 0 or 1 — indicates to which module — master or slave, respectively — the command in the CMD field (of the CMD\_TX\_DATA\_REG) is sent. The master module can be sent a master command only; the slave module can be sent a slave command only (see "Master module and slave module commands," beginning on page 455, for a list of commands). If a command is sent to the master module, that module is locked until a command acknowledgement is given. Similarly, if a command is sent to the slave module, the slave module is locked until it receives a command acknowledgement. With either module, the acknowledgement can be any interrupt associated with that module. When a module is locked, another command must not be sent to that module.

The command lock status can be checked in the STATUS\_RX\_DATA\_REG.

### Master module and slave module commands

The I<sup>2</sup>C master recognizes four high-level commands, which are used in the CMD field of the Command register; the I<sup>2</sup>C slave recognizes two high-level commands:

Command	Name	Description
0x0	M_NOP	No operation.
0x4	M_READ	Start reading bytes from slave.
0x5	M_WRITE	Start writing bytes to slave.
0x6	M_STOP	Stop this transaction (give up the I <sup>2</sup> C bus).
0x10	S_NOP	No operation. This command is necessary for 16-bit mode, providing data in TX_DATA_REG without a command.
0x16	S_STOP	Stop transaction by not acknowledging the byte received.

### Bus arbitration

Any M\_READ or M\_WRITE command causes the I<sup>2</sup>C module to participate in the bus arbitration process when the I<sup>2</sup>C bus is free (idle). If the module becomes the new

bus owner, the transaction goes through. If the module loses bus arbitration, an M\_ARBIT\_LOST interrupt is generated to the host processor and the command must be reissued.

## I<sup>2</sup>C registers

All registers have 8-bit definitions, but must be accessed in pairs. For example, TX\_DATA\_REG and CMD\_REG are written simultaneously and RX\_DATA\_REG and STATUS\_REG are read simultaneously.

### Register address map

This table shows the register addresses. All configuration registers must be accessed as 32-bit words and as single accesses only. Bursting is not allowed.

Register	Description
9005 0000	Command Transmit Data register (CMD_TX_DATA_REG) Status Receive Data register (STATUS_RX_DATA_REG)
9005 0004	Master Address register
9005 0008	Slave Address register
9005 000C	Configuration register

After a reset, all registers are set to the initial value. If an unspecified register or bit is read, a zero is returned.

## Command Transmit Data register

Address: 9005 0000

The Command Transmit Data (CMD\_TX\_DATA\_REG) register is the primary interface register for transmission of data between the I/O hub and I<sup>2</sup>C bus. This register is write only.

### Register

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:16	N/A	Reserved	N/A	N/A
D15	W	PIPE	0x0	Pipeline mode Must be set to 0.
D14	W	DLEN	0x0	<b>I<sup>2</sup>C DLEN port</b> (iic_dlen) Must be set to 0.
D13	W	TXVAL	0x0	<b>Provide new transmit data in</b> CMD_TX_DATA_REG (tx_data_val).
D12:08	W	CMD	0x0	Command to be sent (see "Master module and slave module commands," beginning on page 455)
D07:00	W	TXDATA	0x0	Transmit data to I <sup>2</sup> C bus.

## Status Receive Data register

Address: 9005 0000

The Status Receive Data register (STATUS\_RX\_DATA\_REG) is the primary interface register for receipt of data between the I/O hub and I<sup>2</sup>C bus. This register is read only.

## Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D11	R/W	GCA	0x0	General call address ( <code>s_gca_irq_en</code> ) Enable the general call address.
D10:01	R/W	SDA	0x3FF	Slave device address Represents bits 6:0 of device address if using 7-bit address; D10:08 are not used. Represents bits 9:0 of device address if using 10-bit address.
D00	R/W	SAM	0x0	Slave addressing mode 07 bit address mode 110 bit address mode

## Configuration register

Address: 9005 000C

The Configuration register controls the timing on the I<sup>2</sup>C bus. This register also controls the external interrupt indication, which can be disabled.

The I<sup>2</sup>C bus clock timing is programmable by the scl\_ref value (D08:00). The timing parameter for standard mode is as follows:

$$I^2C\_bus\_clock = clk / ((CLREF*2) + 4 + scl\_delay)$$

$$clk = PLL\ Clk\ Out/4$$

**Notes:** To determine the “PLL Clk Out” frequency, see the “PLL configuration and control system block diagram” on page 151 and the “PLL Configuration register” on page 185. In noisy environments and fast-mode transmission, spike filtering can be applied to the received I<sup>2</sup>C data and clock signal. The spike filter evaluates the incoming signal and suppresses spikes. The maximum length of the suppressed spikes can be specified in the spike filter width field of the Configuration register.

### Timing parameter for fast-mode

This is the timing parameter for fast-mode:

$$I^2C\_bus\_clock = (4 / 3) \times (clk / ((CLREF*2) + 4 + scl\_delay))$$

scl\_delay is influenced by the SCL rise time.

### Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

### Register bit assignment

Bits	Access	Mnemonic	Reset	Description
D31:16	N/A	Reserved	N/A	N/A
D15	R/W	IRQD	0	<b>Mask the interrupt to the ARM CPU</b> (irq_dis) Must be set to 0.
D14	R/W	TMDE	1	Timing characteristics of serial data and serial clock 0Standard mode 1Fast mode
D13	R/W	VSCD	1	Virtual system clock divider for master and slave Must be set to 0.

Bits	Access	Mnemonic	Reset	Description
D12:09	R/W	SFW	0xF	Spike filter width A default value of 1 is recommended. Available values are 0–15.
D08:00	R/W	CLREF	0x0	clk_ref[9:1] The I2C clock on port iic_scl_out is generated by the system clock divided by the 10-bit value of clk_ref. The LSB of clk_ref cannot be programmed, and is set to 0 internally. The programmed value of clk_ref[9:1] must be greater than 3.

## Interrupt Codes

Interrupts are signaled in the `irq_code` field in the `STATUS_REG`, by providing the appropriate interrupt code (see “Master/slave interrupt codes” on page 461). The ARM CPU waits for an interrupt by polling the `STATUS_REG` or checking the `irq` signal. An interrupt is cleared by reading the `STATUS_REG`, which also forces the `irq` signal down (minimum one cycle if another interrupt is stored).

**Note:** `RX_DATA_REG` contains only a received byte if it is accessed after a `RX_DATA` master or slave interrupt is signaled. At all other times, the internal master or slave shift register is accessed with `RX_DATA_REG` (see “Status Receive Data register” on page 457).

### Master/slave interrupt codes

Code	Name	Master/slave	Description
0x0	NO_IRQ	N/A	No interrupt active
0x1	M_ARBIT_LOST	Master	Arbitration lost; the transfer has to be repeated
0x2	M_NO_ACK	Master	No acknowledge by slave
0x3	M_TX_DATA	Master	TX data required in register <code>TX_DATA</code>
0x4	M_RX_DATA	Master	RX data available in register <code>RX_DATA</code>
0x5	M_CMD_ACK	Master	Command acknowledge interrupt
0x6	N/A	N/A	Reserved
0x7	N/A	N/A	Reserved
0x8	S_RX_ABORT	Slave	The transaction is aborted by the master before the slave performs a <code>NO_ACK</code> .
0x9	S_CMD_REQ	Slave	Command request
0xA <sub>x</sub>	S_NO_ACK	Slave	No acknowledge by master ( <code>TX_DATA_REG</code> is reset)

Code	Name	Master/slave	Description
0xB	S_TX_DATA_1ST	Slave	TX data required in register TX_DATA, first byte of transaction
0xC	S_RX_DATA_1ST	Slave	RX data available in register RX_DATA, first byte of transaction
0xD	S_TX_DATA	Slave	TX data required in register TX_DATA
0xE	S_RX_DATA	Slave	RX data available in register RX_DATA
0xF	S_GCA	Slave	General call address

## Software driver

### I<sup>2</sup>C master software driver

The I<sup>2</sup>C master software driver uses three commands only:

- M\_READ to start a read sequence
- M\_WRITE to start a write sequence
- M\_STOP to give up the I<sup>2</sup>C bus

If, during a read or write sequence, another M\_READ or M\_WRITE is requested by the ARM CPU, a restart is performed on the I<sup>2</sup>C bus. This opens the opportunity to provide a new slave device address in the MAster Address register before the command request.

### I<sup>2</sup>C slave high level driver

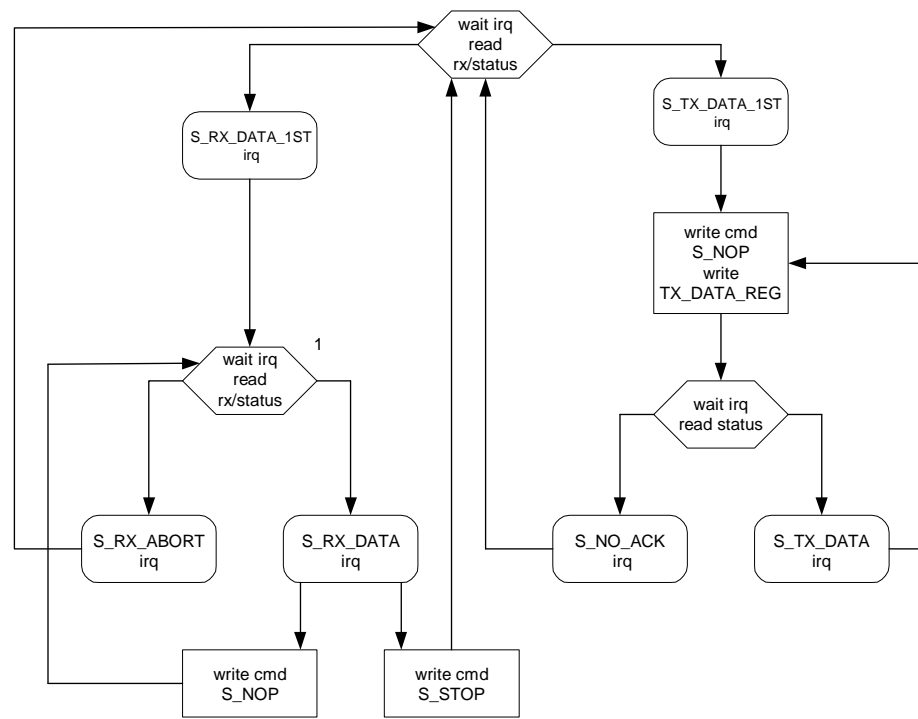

The I<sup>2</sup>C slave high level driver identifies one command: S\_STOP, to discontinue a transaction. After this command, the slave remains inactive until the next start condition on the I<sup>2</sup>C bus. If a slave is accessed by a master, it generates S\_RX\_DATA and S\_TX\_DATA interrupts (see “Master/slave interrupt codes” on page 461). To distinguish the transactions from each other, special S\_RX\_DATA\_1ST and S\_TX\_DATA\_1ST interrupts are generated for the transmitted byte.

### Slave module (normal mode, 16-bit)

**Note:** STATUS\_REG and RX\_DATA\_REG are read simultaneously.

# Real Time Clock Module

## C H A P T E R 1 4

The Real Time Clock (RTC) module tracks the time of the day to an accuracy of 10 milliseconds and provides calendar functionality that tracks day, month, and year.

### RTC functionality

RTC monitors these time periods:

- Year from 1900-2999
- Month from 1-12
- Date from 1-28, 29, 30, or 31, as a function of year and month
- Day of week from 1-7
- Hour from 0-23, or from 1-12 with the AM/PM flag set
- Minute from 0-59
- Second from 0.00-59.99

RTC functionality also provides an alarm register that allows comparison of month, date, hour, minute, second, and hundredth-second. Each item can be masked, allowing an alarm to be generated at a particular time and date on a monthly basis. An interrupt can be generated on the alarm event.

Event detection finds and generates interrupts on rollover conditions, including rollovers into a new month, date, hour, minute, second, or hundredth-second.

### RTC configuration and status registers

All configuration registers must be accessed as 32-bit words and as single accesses only. Bursting is not allowed.

### Register address map

Address	Description
9006 0000	RTC General Control register
9006 0004	12/24 Hour register
9006 0008	Time register

Address	Description
9006 000C	Calendar register
9006 0010	Time Alarm register
9006 0014	Calendar Alarm register
9006 0018	Alarm Enable register
9006 001C	Event Flags register
9006 0020	Interrupt Enable register
9006 0024	Interrupt Disable register
9006 0028	Interrupt Status register
9006 002C	General Status register

The reset values listed in the register descriptions are set when the regulated battery voltage on pins N3 and M4 drops below 1.56V.

## RTC General Control register

Address: 9006 0000

The RTC General Control register contains miscellaneous settings for the RTC module.

### Register

## Alarm Enable register

Address: 9006 0018

The Alarm Enable register sets the fields that can trigger an alarm. Setting a bit enables the corresponding time unit trigger event. Triggering the alarm causes an event to be generated, as set in the Events Flag register.

If all fields are enabled, an alarm is generated at the time set — the specific month, date, hour, minute, second, and hundredth-second. If only the minute field is set, the alarm triggers when that particular minute is reached, and every hour thereafter.

## Register

## Register bit assignment

Bits	Access	Mnemonic	Reset	Description

# *Analog-to-Digital Converter (ADC) Module*

## C H A P T E R 1 5

The NS9215 ASIC supports a 12-bit successive approximation analog-to-digital converter (ADC). To maximize flexibility, an input pin is provided to apply an external reference voltage, which defines the full scale input range. An analog multiplexer is included to enable the selection of up to eight inputs.

### Features

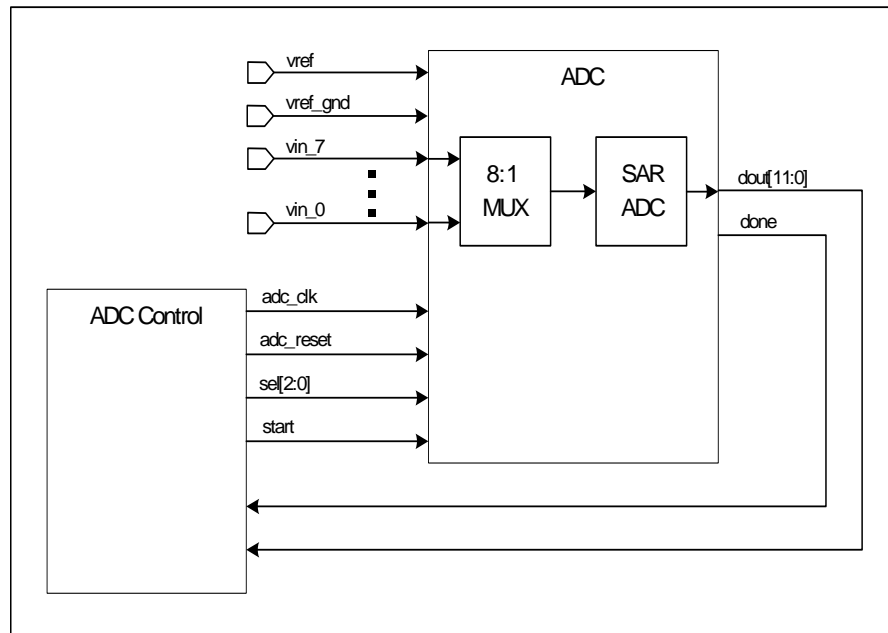

The ADC module supports these features:

- 12-bit resolution
- 1 MHz conversion rate
- Single-ended 8:1 multiplexed inputs
- Rail-to-rail input range
- 12-bit output, either DMA or direct CPU access

### ADC module structure

This diagram shows the ADC module structure.

### ADC control block

The ADC control block provides access between the CPU and the ADC module. The ADC clock and control signals are generated in this block. The ADC module output can be either DMA'd to memory or read directly by the CPU.

- If DMA is enabled, ADC output data is written to memory using UART D's receive DMA controller.
- If more than one channel is enabled, word 0 in the DMA buffer will always be from channel 0, followed by the data from the other selected channels.
- The data buffer length must be a word multiple of the number of selected channels. For example, if three channels are selected, the buffer length must be a multiple of three words or 12 bytes.

### ADC DMA procedure

If using DMA, the DMA channel must be set up first and enabled before enabling the ADC. The procedure below must be followed each time a new DMA is started or if a DMA FIFO overflow is detected. The RX FIFO overflow interrupt should be enabled to detect an overflow.

- 1 Configure the ADC Configuration register at address 9003 9000 for DMA operation (bit 3 set to 1) and the number of channels but leave bit 31 set to a 0.

- 2 Set up the ADC DMA control registers and buffer descriptors (UART channel D).
- 3 Reset the ADC module by writing a 0 then a 1 to bit 8 in the Module Reset register at address A090 0180.
- 4 Flush the ADC DMA FIFO by writing a 1 then a 0 to bit 17 in UART Channel D Wrapper Configuration register at address 9002 9000.
- 5 Enable the ADC DMA channel by writing a 1 then a 0 to bit 31 in the UART D DMA RX Control register at address 9002 8004. 6. Start the ADC by writing a 1 to bit 31 in the ADC Configuration register at address 9003 9000.

## ADC control and status registers

The ADC configuration registers are located at offset 0x9003\_9000.

### Register address map

Address	Description	Access	Reset value
9003_9000	ADC Configuration register	R/W	0x00000000
9003_9004	ADC Clock Configuration register	R/W	0x00000000
9003_9008	ADC Output 0 register	R/W	0x00000000
9003_900C	ADC Output 1 register	R/W	0x00000000
9003_9010	ADC Output 2 register	R/W	0x00000000
9003_9014	ADC Output 3 register	R/W	0x00000000
9003_9018	ADC Output 4 register	R/W	0x00000000
9003_901C	ADC Output 5 register	R/W	0x00000000
9003_9020	ADC Output 6 register	R/W	0x00000000
9003_9024	ADC Output 7 register	R/W	0x00000000

## ADC Configuration register

Address: 9003\_9000

The ADC Configuration register is the primary Wrapper Configuration register.

## Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADCEN	Reserved												INSTAT		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											INTCLR	DMAEN	SEL		

## Register bit assignment

Bit(s)	Access	Mnemonic	Reset	Description
D31	R/W	ADCEN	0	0 The ADC module is disabled and held in reset 1 The ADC module is enabled
D30:19	N/A	Reserved	N/A	N/A
D18:16	R	INSTAT	0	<b>Interrupt status</b> Indicates the channel processed at the time of the interrupt.
D15:5	N/A	Reserved	N/A	N/A
D04	R/W	INTCLR	0	<b>Interrupt clear</b> The ADC module generates an interrupt each time the ADC generates a new value. This bit clears the interrupt. The CPU must write a 1, then a 0 to this bit to clear the interrupt.
D03	R/W	DMAEN	0	<b>DMA enable</b> If set, ADC output data is written to memory using UART D's receive DMA. 0 DMA disabled 1 DMA enabled
D02:00	R/W	SEL	000	<b>ADC channel select</b> Controls how many channels are active. 000 Channel 0 001 Channels 0-1 010 Channels 0-2 011 Channels 0-3 100 Channels 0-4 101 Channels 0-5 110 Channels 0-6 111 Channels 0-7

## ADC Clock Configuration register

Address: 9003\_9004

The ADC Clock Configuration register controls the ADC clock generator. The source clock is the output of the PLL. The maximum allowed ADC clock frequency is 14 MHz. The ADC takes 14 cycles to convert each sample. So, for example, if the ADC clock frequency is 14 MHz, then the actual sampling rate is 1 MHz.

These are the formulas for the clock rates:

- $\text{ADC Clock} = \text{PLL clock} / (2 \times (N+1))$
- $\text{Sampling Rate} = (\text{ADC Clock})/14$

Solving for N given a specific ADC Clock rate or sampling rate yields these formulas:

- $N = \text{PLL clock} / (2 \times \text{ADC Clock}) - 1$
- $N = \text{PLL clock} / (28 \times \text{Sampling Rate}) - 1$

### Example

PLL clock frequency = 299.8272 MHz

N value = 10

ADC clock frequency:

$\text{ADC clock} = 299.8272 \text{ MHz} / (2 \times (10+1)) = 13.6285 \text{ MHz}$

N must be set to 10 or more at the 299.8272 MHz PLL clock rate since smaller values of N would cause the ADC clock frequency to be higher than 14 MHz.

Wait states can be added to increase conversion time beyond 14 clock cycles.

### Register

### Register bit assignment

Bit(s)	Access	Mnemonic	Reset	Description
D31:16	R/W	WAIT	N/A	Number of additional clock cycles per conversion cycle.

Bit(s)	Access	Mnemonic	Reset	Description
D15:10	R/W	Not used	0	This field must be written to 0.
D09:00	R/W	N	0	ADC clock converter.

## ADC Output Registers 0-7

Addresses: 9003\_9008 / 9003\_900C / 9003\_9010 / 9003\_9014 / 9003\_9018 / 9003\_901C / 9003\_9020 / 9003\_9024

The ADC Output registers provide CPU access for the ADC output for each channel.

### Register

### Register bit assignment

Bit(s)	Access	Mnemonic	Reset	Description
D31:12	R/W	Not used	0	This field must be written to 0.
D11:00	R	DOUT	0	Provides the output of the ADC for each channel.

# Timing

## C H A P T E R 1 6

This chapter provides the electrical specifications, or timing, integral to the operation of the processor. Timing includes information about DC and AC characteristics, output rise and fall timing, and crystal oscillator specifications.

### Electrical characteristics

#### Absolute maximum ratings

The processor operates at a 1.8V core, with 3.3V I/O ring voltages.

Permanent device damage can occur if absolute maximum ratings are ever exceeded. Absolute maximum ratings are below.

Parameter	Symbol <sup>a</sup>	Rating	Unit
DC supply voltage	V <sub>DDA</sub>	- 0.3 to + 3.9	V
DC input voltage	V <sub>INA</sub>	-0.3 to 5.0V	V
DC output voltage	V <sub>OUTA</sub>	-0.3 to V <sub>DDA</sub> +0.3	V
DC input current	I <sub>IN</sub>	± 10	mA
DC core voltage	V <sub>DDC</sub>	-0.3 to +1.98	V
Junction temperature	T <sub>J</sub>	125	°C
Storage temperature	T <sub>STG</sub>	- 40 to + 125	°C

<sup>a</sup>V<sub>DDA</sub>, V<sub>INA</sub>, V<sub>OUTA</sub>: Ratings of I/O cells for 3.3V interface.

V<sub>DDC</sub>: Ratings of internal cell.

The processor is immune to power supply sequencing problems.

## Recommended operating conditions

Recommended operating conditions specify voltage and temperature ranges over which a circuit's correct logic function is guaranteed. The specified DC electrical characteristics are satisfied over these ranges. Below are the recommended operating conditions.

Parameter	Symbol <sup>a</sup>	Rating	Unit
3.3V I/O voltage	V <sub>DDA</sub>	3.0 to 3.6	DC volts
1.8V core voltage	V <sub>DDC</sub>	1.71 to 1.89	DC volts
Operating temperature		-40 to +85	°C

a V<sub>DDA</sub>: Ratings of I/O cells for 3.3V interface.

V<sub>DDC</sub>: Ratings of internal cells

## Power dissipation

- Theta Ja = 31.7 °C/W

$$T_j = T_a + (\text{Theta Ja} \times W)$$

T<sub>j</sub> = Temperature junction

T<sub>a</sub> = Temperature ambient

Theta Ja = Junction to ambient

W = Power in Watts

Junction-to-ambient thermal resistance is a measure of the ability of a device to dissipate heat from the surface of the die to ambient via all paths.

- Psi-jt = 2.5 °C/W

$$T_j = T_c + (\text{psi} \times W)$$

T<sub>j</sub> = Temperature junction

T<sub>c</sub> = Case Temperature

Psi = Thermal coefficient tying the case to the junction

W = Power in Watts

Psi-jt is measured at the top of the package in the center. Under natural convection, psi-jt for a plastic package is generally a relatively low value. This means that T<sub>j</sub> is usually just a little hotter than the top of the package. The die is physically separated from the top surface by only a thin region of plastic mold compound. So unless the top is forcibly cooled by significant airflow there will be very little delta-T between them.

The table below shows the maximum power dissipation for I/O and core:

CPU / Memory clock	Power
150MHz/75MHz FIMs On	Total 1.019W Core 0.880W I/O 0.139W
75 MHz/75MHz FIMs On	Total 0.828W Core 0.696W I/O 0.132W
112MHz/56MHz FIMs Off	Total 0.638W Core 0.536W I/O 0.102W
56MHz/56MHz FIMs Off	Total 0.499W Core 0.403W I/O 0.096W
Sleep Mode, wake on Ethernet	Total 0.073W Core 0.027W I/O 0.046W
Sleep Mode, wake on External IRQ	Total 0.055W Core 0.022W I/O 0.033W
Main Power Down, Battery Draw	3.0V - 32uA 1.8V - 6uA

## DC electrical characteristics

DC characteristics specify the worst-case DC electrical performance of the I/O buffers that are guaranteed over the specified temperature range.

### Inputs

All electrical inputs are 3.3V interface.

The processor I/O are 5 volt tolerant.

DC electrical inputs are provided below.

Sym	Parameter	Condition <sup>a</sup>	Value		Unit
$V_{IH}$	High-level input voltage: LVTTL level		Min	2.0	V
$V_{IL}$	Low-level input voltage: LVTTL level		Max	0.8	V
$I_{IH}$	High level input current (no pulldown) Input buffer with pulldown (equivalent to 16.5K)	$V_{INA} = V_{DDA}$	Min/Max	-10/10	$\mu A$
			Min/Max	10/200	$\mu A$
$I_{IL}$	Low-level input current (no pullup) Input buffer with pullup (equivalent to 16.5K)	$V_{INA} = V_{SS}$	Min/Max	-10/10	$\mu A$
			Min/Max	10/200	$\mu A$
$I_{OZ}$	High-impedance leakage current	$V_{OUTA} = V_{DDA}$ or $V_{SS}$	Min/Max	-10/10	$\mu A$

<sup>a</sup>  $V_{SS} = 0V$  (GND);  $V_{INA}$  = Voltage in;  $V_{DDA} = 3.3V$

## Outputs

All electrical outputs are 3.3V interface.

DC electrical outputs are provided below.

Sym	Parameter	Value		Unit
$V_{OH}$	High-level output voltage (LVTTL level)	Min	$V_{DDA}-0.6$	V
$V_{IL}$	Low-level output voltage: LVTTL level	Max	0.4	V

## Reset and edge sensitive input timing requirements

The critical timing requirement is the rise and fall time of the input. If the rise time is too slow for the reset input, the hardware strapping options may be registered incorrectly. If the rise time of a positive-edge-triggered external interrupt is too slow, then an interrupt may be detected on both the rising and falling edge of the input signal.

A maximum rise and fall time must be met to ensure that reset and edge sensitive inputs are handled correctly. With Digi processors, the maximum is 500 nanoseconds as shown:

## TIMING

### *Reset and edge sensitive input timing requirements*

If an external device driving the reset or edge sensitive input on a Digi processor cannot meet the 500ns maximum rise and fall time requirement, the signal must be buffered with a Schmitt trigger device. Here are sample Schmitt trigger device part numbers:

Manufacturer	Part Number	Description
Fairchild	NC7SP17	Single Schmitt trigger buffer, available in 5-lead SC70 and 6-lead MicroPak packages
Philips	74LVC1G17GW	Single Schmitt trigger buffer, available in 5-lead SC70 and SOT 353 packages
TI	SN74LVC1G17DC	Single Schmitt trigger buffer, available in 5-lead SC70 and SOT 353 packages
ON Semi	NL17SZ17DFT2	Single Schmitt trigger buffer, available in 5-lead SC70 and SOT 353 packages.

## Memory Timing

All memory timing is measured with 25pF, unless otherwise noted.

Memory timing contains parameters and diagrams for both SDRAM and SRAM timing.

The table below describes the values shown in the SDRAM timing diagrams.

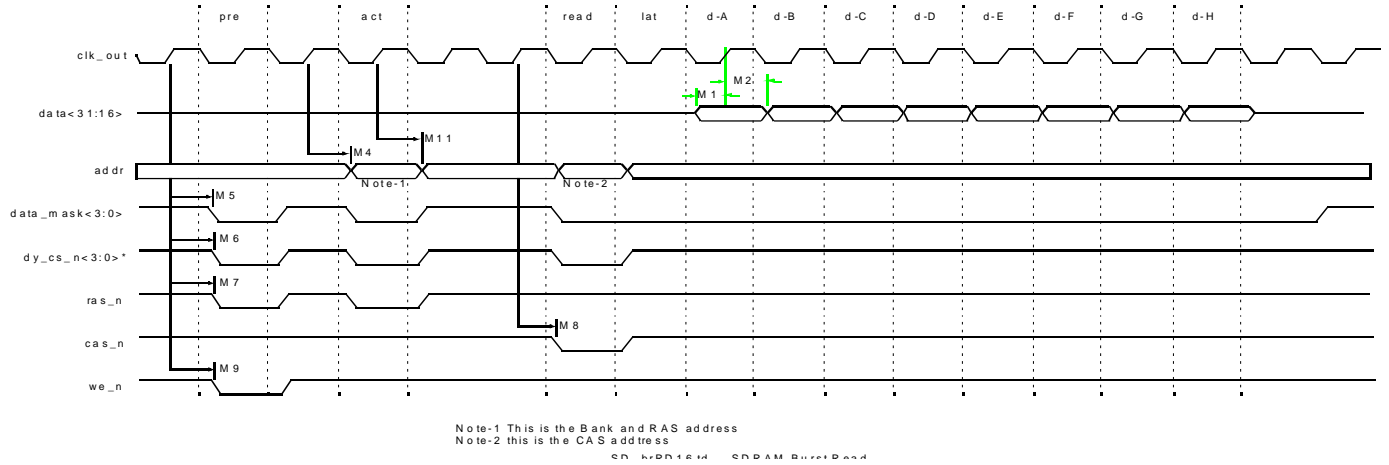

Parm	Description	Min	Max	Unit	Notes
M1	data input setup time to rising	1.0		ns	
M2	data input hold time to rising	0.0		ns	
M4	clk_out high to address valid		9.5	ns	
M11	address hold time	4.0			
M5	clk_out high to data_mask		9.5	ns	1, 2
M6	clk_out high to dy_cs_n low		9.5	ns	3, 4
M7	clk_out high to ras_n low		9.5	ns	
M8	clk_out high to cas_n low		9.5	ns	
M9	clk_out high to we_n low		9.5	ns	
M10	clk_out high to data out		9.5	ns	
M12	data out hold time	4.0			
M3	clk_out high to clk_en high		9.5	ns	
M13	clk_en high to sdram access	2	2	clock	
M14	end sdram access to clk_en low	2	2	clocks	

Notes:

- 1 All four data\_mask signals are used for all transfers.
- 2 All four data\_mask signals will go low during a read cycle, for both 16-bit and 32-bit transfers.
- 3 Only one of the clk\_out signals is used.
- 4 Only one of the dy\_cs\_n signals is used.

**SDRAM burst  
read (16-bit)  
latency = 2**

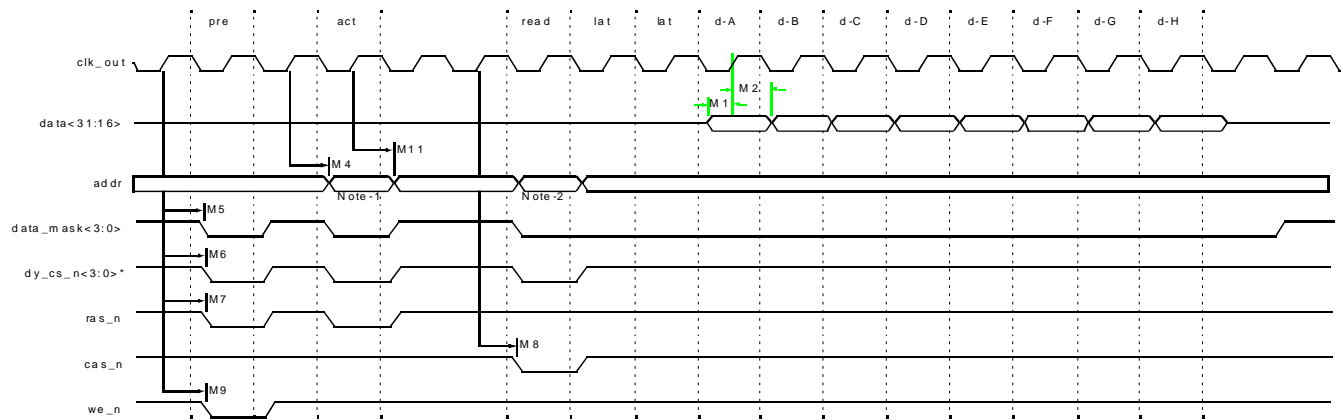

Notes:

- 1 This is the bank and RAS address.
- 2 This is the CAS address.

**SDRAM burst  
read (16 bit), CAS  
latency = 3**

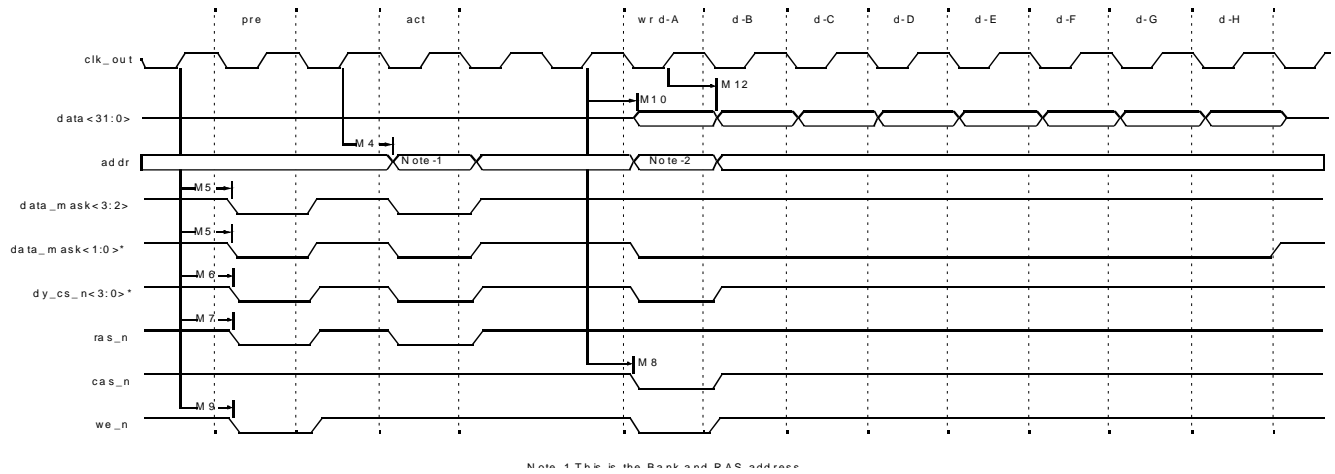

Note-1 This is the Bank and RAS address  
Note-2 this is the CAS address

**Notes:**

- 1 This is the bank and RAS address.
- 2 This is the CAS address.

## SDRAM burst write (16 bit)

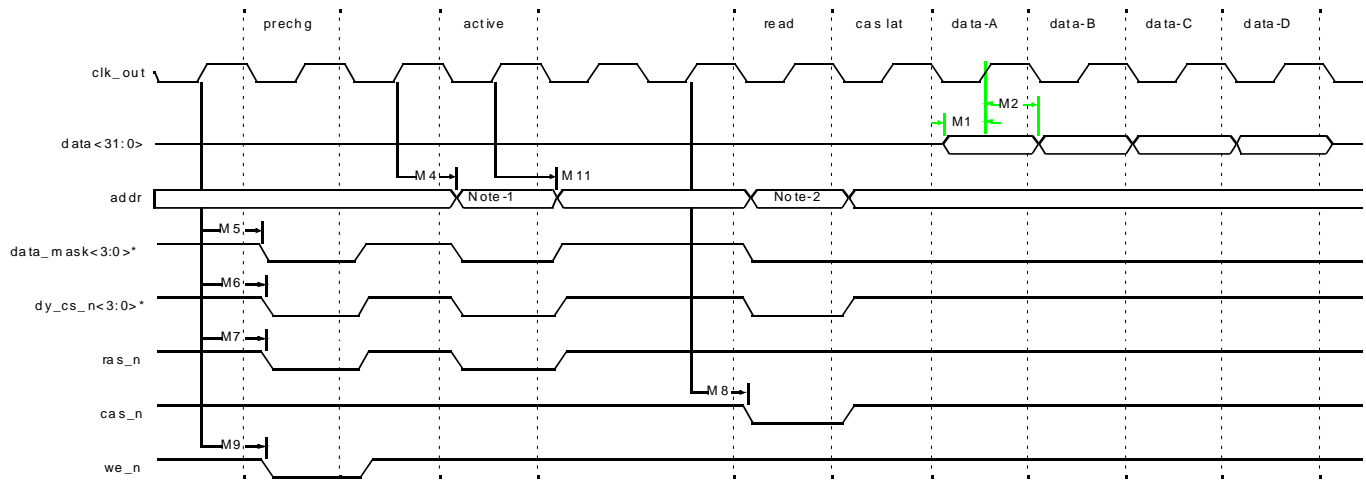

### Notes:

- 1 This is the bank and RAS address.
- 2 This is the CAS address.

## SDRAM burst read (32 bit)

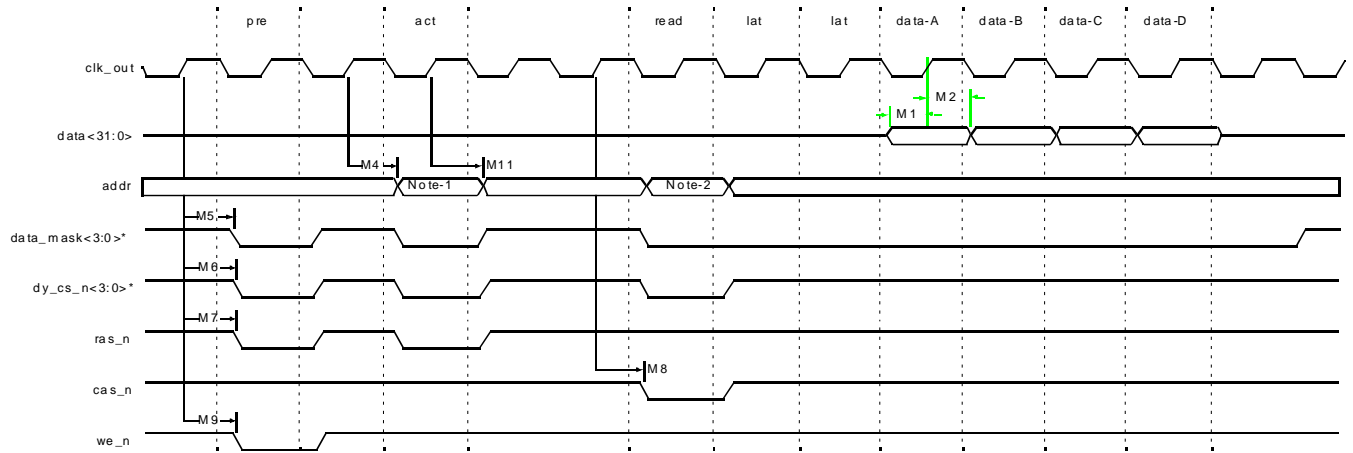

### Notes:

- 1 This is the bank and RAS address.
- 2 This is the CAS address.

**SDRAM burst  
read (32 bit), CAS  
latency = 3**

Notes:

- 1 This is the bank and RAS address.
- 2 This is the CAS address.

## SDRAM burst write (32-bit)

Notes:

- 1 This is the bank and RAS address.
- 2 This is the CAS address.

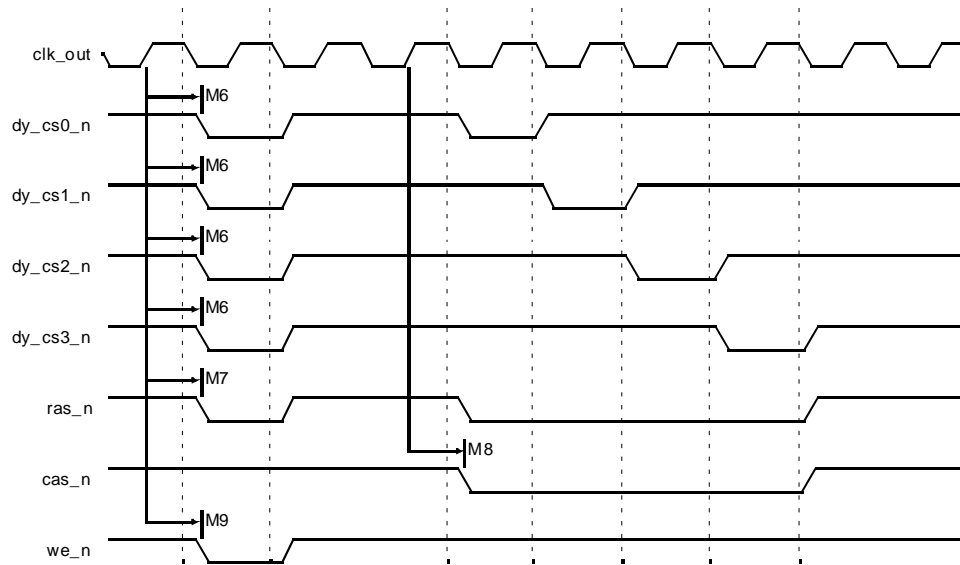

**SDRAM load  
mode**

## SDRAM refresh mode

**Clock enable timing**

## Values in SRAM timing diagrams

The next table describes the values shown in the SRAM timing diagrams.

Parm	Description	Min	Max	Unit	Notes
M15	clock high to data out valid	-2	+2	ns	1
M16	data out hold time from clock high	-2	+2	ns	
M17	clock high to address valid	-2	+2	ns	
M18	address hold time from clock high	-2	+2	ns	
M19	clock high to st_cs_n low	-2	+2	ns	2, 3
M20	clock high to st_cs_n high	-2	+2	ns	2, 3
M21	clock high to we_n low	-2	+2	ns	
M22	clock high to we_n high	-2	+2	ns	
M23	clock high to byte_lanes low	-2	+2	ns	
M24	clock high to byte_lanes high	-2	+2	ns	
M25	data input setup time to rising clk	10		ns	
M26	data input hold time to rising clk	0		ns	
M27	clock high to oe_n low	-2	+2	ns	
M28	clock high to oe_n high	-2	+2	ns	

Notes:

- 1 The clk\_out signal is for reference only.
- 2 Only one of the four st\_cs\_n signals is used. The diagrams show the active low configuration, which can be reversed (active high) with the PC field.
- 3 Use this formula to calculate the length of the st\_cs\_n signal:  $T_{acc} + \text{board delay} + (\text{optional buffer delays, both address out and data in}) + 10\text{ns}$

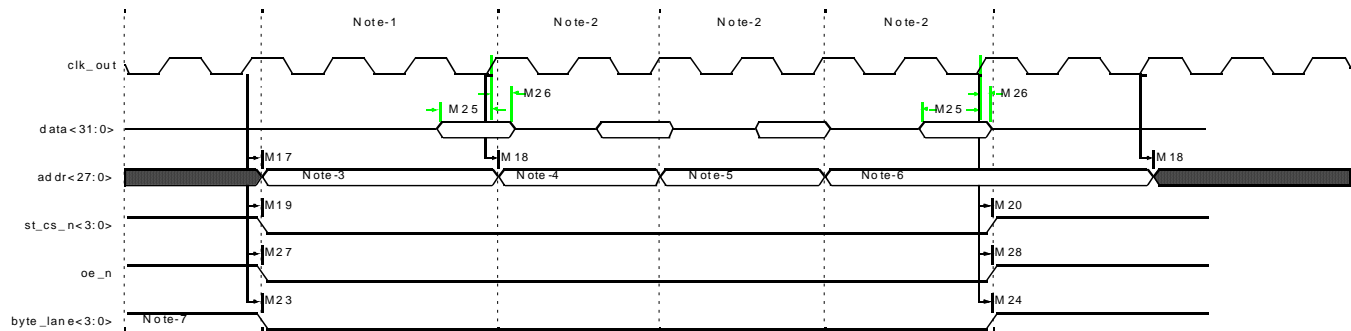

### Static RAM read cycles with 1 wait states

- WTRD = 1
- WOEN = 0
- If the PB field is set to 1, all four byte\_lane signals will go low for 32-bit, 16-bit, and 8-bit read cycles.
- If the PB field is set to 0, the byte\_lane signal will always be high.

Static RAM  
asynchronous  
page mode read,  
WTPG = 1

- WTPG = 1
- WTRD = 2
- If the PB field is set to 1, all four byte\_lane signals will go low for 32-bit, 16-bit, and 8-bit read cycles.
- The asynchronous page mode will read 16 bytes in a page cycle. A 32-bit bus will do four 32-bit reads, as shown (3-2-2-2). A 16-bit bus will do eight 16-bit reads (3-2-2-2-3-2-2-2) per page cycle, and an 8-bit bus will do sixteen 8-bit reads (3-2-2-2-3-2-2-2-3-2-2-2-3-2-2-2) per page cycle. 3-2-2-2 is the example used here, but the WTRD and WTPG fields can set them differently.

Notes:

- 1 The length of the first cycle in the page is determined by the WTRD field.
- 2 The length of the 2nd, 3rd, and 4th cycles is determined by the WTPG field.
- 3 This is the starting address. The least significant two bits will always be '00.'
- 4 The least significant two bits in the second cycle will always be '01.'
- 5 The least significant two bits in the third cycle will always be '10.'
- 6 The least significant two bits in the fourth cycle will always be '11.'
- 7 If the PB field is set to 0, the byte\_lane signal will always be high during a read cycle.
- 8 Setting the BMODE (Burst mode) bit D02 in the static memory configuration register allows the static output enable signal to toggle during bursts.

### Static RAM read cycle with configurable wait states

- WTRD = from 1 to 15
- WOEN = from 0 to 15
- If the PB field is set to 1, all four **byte\_lane** signals will go low for 32-bit, 16-bit, and 8-bit read cycles.
- If the PB field is set to 0, the **byte\_lane** signal will always be high.

## Static RAM sequential write cycles

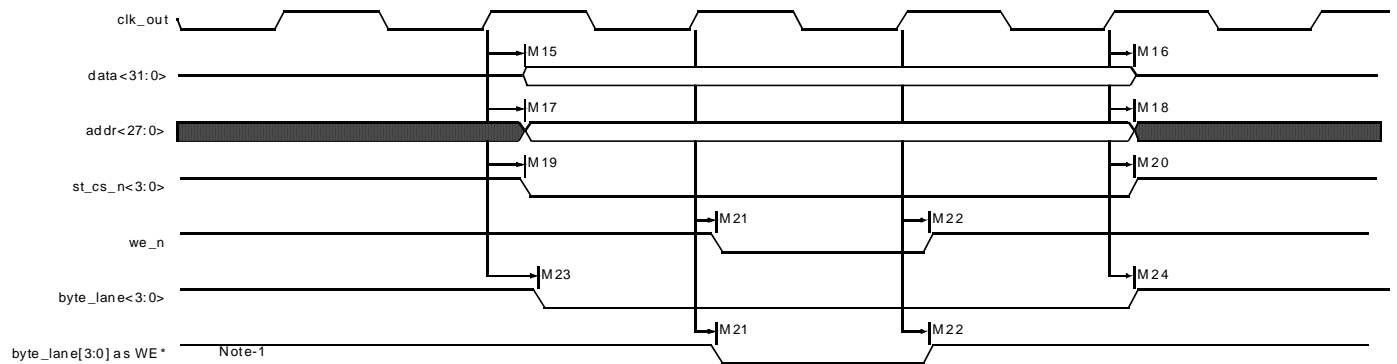

- $WTWR = 0$
- $WWEN = 0$
- During a 32-bit transfer, all four `byte_lane` signals will go low.
- During a 16-bit transfer, two `byte_lane` signals will go low.
- During an 8-bit transfer, only one `byte_lane` signal will go low.

Note:

If the PB field is set to 0, the `byte_lane` signals will function as write enable signals and the `we_n` signal will always be high.

## Static RAM write cycle

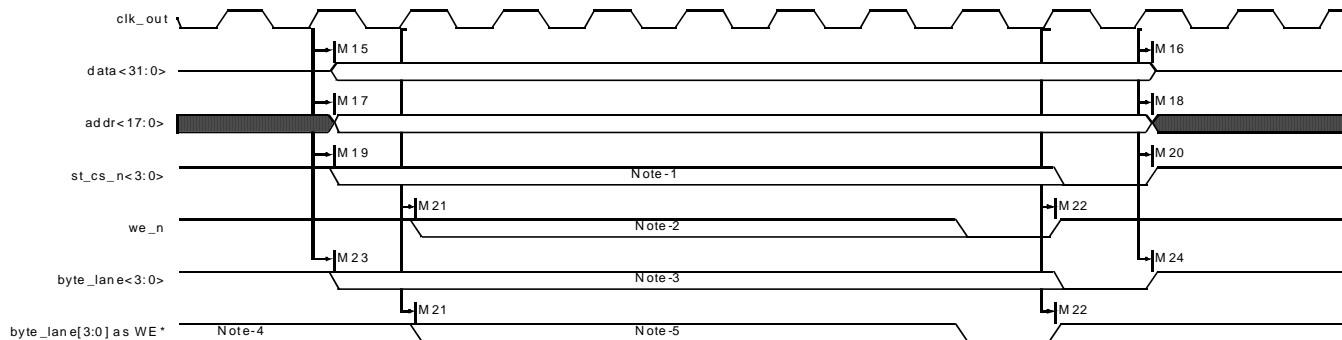

- WTWR = 0
- WWEN = 0
- During a 32-bit transfer, all four byte\_lane signals will go low.
- During a 16-bit transfer, two byte\_lane signals will go low.
- During an 8-bit transfer, only one byte\_lane signal will go low.

Note:

If the PB field is set to 0, the byte\_lane signals will function as write enable signals and the we\_n signal will always be high.

## Static write cycle with configurable wait states

- WTWR = from 0 to 15
- WWEN = from 0 to 15
- The WTWR field determines the length on the write cycle.
- During a 32-bit transfer, all four `byte_lane` signals will go low.
- During a 16-bit transfer, two `byte_lane` signals will go low.
- During an 8-bit transfer, only one `byte_lane` signal will go low.

### Notes:

- 1 Timing of the `st_cs_n` signal is determined with a combination of the WTWR and WWEN fields. The `st_cs_n` signal will always go low at least one clock before `we_n` goes low, and will go high one clock after `we_n` goes high.
- 2 Timing of the `we_n` signal is determined with a combination of the WTWR and WWEN fields.
- 3 Timing of the `byte_lane` signals is determined with a combination of the WTWR and WWEN fields. The `byte_lane` signals will always go low one clock before `we_n` goes low, and will go one clock high after `we_n` goes high.
- 4 If the PB field is set to 0, the `byte_lane` signals will function as the write enable signals and the `we_n` signal will always be high.
- 5 If the PB field is set to 0, the timing for the `byte_lane` signals is set with the WTWR and WWEN fields.

### Slow peripheral acknowledge timing

The table below describes the values shown in the slow peripheral acknowledge timing diagrams.

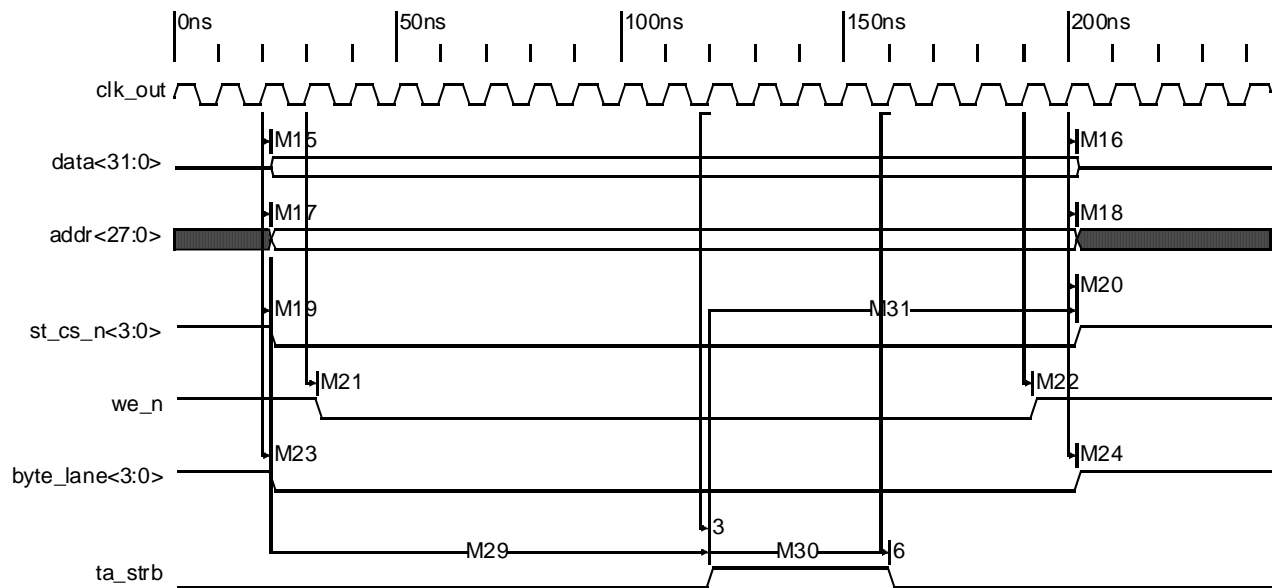

Parm	Description	Min	Max	Unit	Notes
M15	clock high to data out valid	-2	+2	ns	
M16	data out hold time from clock high	-2	+2	ns	
M17	clock high to address valid	-2	+2	ns	
M18	address hold time from clock high	-2	+2	ns	
M19	clock high to st_cs_n low	-2	+2	ns	
M20	clock high to st_cs_n high	-2	+2	ns	
M21	clock high to we_n low	-2	+2	ns	
M22	clock high to we_n high	-2	+2	ns	
M23	clock high to byte_lanes low	-2	+2	ns	
M24	clock high to byte_lanes high	-2	+2	ns	
M26	data input hold time to rising clk	0		ns	
M27	clock high to oe_n low	-2	+2	ns	
M28	clock high to oe_n high	-2	+2	ns	
M29	address/chip select valid to ta_strb high	2		CPU cycles	
M30	ta_strb pulse width	4	8	CPU cycles	
M31	ta_strb rising to chip select/address change	4	10	CPU cycles	
M32	data setup to ta_strb rising	0		ns	

### Slow peripheral acknowledge read

### Slow peripheral acknowledge write

## Ethernet timing

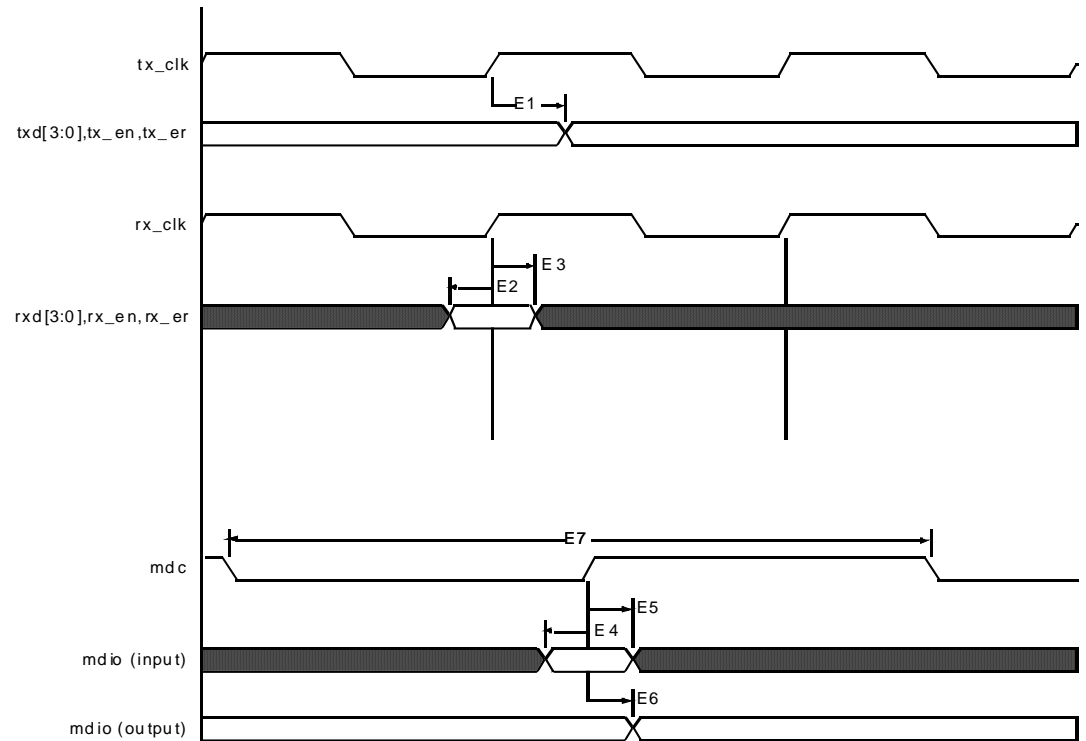

All AC characteristics are measured with 10pF, unless otherwise noted.  
The table below describes the values shown in the Ethernet timing diagrams.

Parm	Description	Min	Max	Unit	Notes
E1	MII tx_clk to txd, tx_en, tx_er	3	11	ns	2
E2	MII rxd, rx_en, rx_er setup to rx_clk rising	3		ns	
E3	MII rxd, rx_en, rx_er hold from rx_clk rising	1		ns	
E4	mdio (input) setup to mdc rising	10		ns	
E5	mdio (input) hold from mdc rising	0		ns	2
E6	mdc to mdio (output)	18	34	ns	1, 2
E7	mdc period	80		ns	3

Notes:

- 1 Minimum specification is for fastest AHB bus clock of 75 MHz. Maximum specification is for slowest AHB bus clock of 37.5 MHz.
- 2  $C_{load} = 10\text{pf}$  for all outputs and bidirects.
- 3 Minimum specification is for fastest AHB clock at 75 MHz.

## Ethernet MII timing

## I<sup>2</sup>C timing

All AC characteristics are measured with 10pF, unless otherwise noted.

The table below describes the values shown in the I<sup>2</sup>C timing diagram.

Parm	Description	Standard Mode		Fast Mode		Unit
		Min	Max	Min	Max	
C1	iic_sda to iic_scl START hold time	4.0		0.6		μS
C2	iic_scl low period	4.7		1.3		μS
C3	iic_scl high period	4.7		1.3		μS
C4	iic_scl to iic_sda DATA hold time	0		0		μS
C5	iic_sda to iic_scl DATA setup tim	250		100		μS
C6	iic_scl to iic_sda START	4.7		0.6		μS
C7	iic_scl to iic_sda STOP setup time	4.0		0.6		μS

## SPI Timing

All AC characteristics are measured with 10pF, unless otherwise noted.  
The next table describes the values shown in the SPI timing diagrams.

Parm	Description	Min	Max	Unit	Mod es	Not es
<b>SPI master parameters</b>						
SPO	SPI enable low setup to first SPI CLK out rising	$3 \cdot T_{BCLK} - 10$		ns	0,3	1,3
SP1	SPI enable low setup to first SPI CLK out falling	$3 \cdot T_{BCLK} - 10$		ns	1,2	1,3
SP3	SPI data in setup to SPI CLK out rising	30		ns	0,3	
SP4	SPI data in hold from SPI CLK out rising	0		ns	0,3	
SP5	SPI data in setup to SPI CLK out falling	30		ns	1,2	
SP6	SPI data in hold from SPI CLK out falling	0		ns	1,2	
SP7	SPI CLK out falling to SPI data out valid		10	ns	0,3	6
SP8	SPI CLK out rising to SPI data out valid		10	ns	1,2	6
SP9	SPI enable low hold from last SPI CLK out falling	$3 \cdot T_{BCLK} - 10$		ns	0,3	1,3
SP10	SPI enable low hold from last SPI CLK out rising	$3 \cdot T_{BCLK} - 10$		ns	1,2	1,3
SP11	SPI CLK out high time	$SP13 \cdot 45\%$	$SP13 \cdot 55\%$	ns	0,1,2, 3	4
SP12	SPI CLK out low time	$SP13 \cdot 45\%$	$SP13 \cdot 55\%$	ns	0,1,2, 3	4
SP13	SPI CLK out period	$T_{BCLK} \cdot 6$		ns	0,1,2, 3	3
<b>SPI slave parameters</b>						
SP14	SPI enable low setup to first SPI CLK in rising	30		ns	0,3	1
SP15	SPI enable low setup to first SPI CLK in falling	30		ns	1,2	1
SP16	SPI data in setup to SPI CLK in rising	0		ns	0,3	
SP17	SPI data in hold from SPI CLK in rising	60		ns	0,3	
SP18	SPI data in setup to SPI CLK in falling	0		ns	1,2	
SP19	SPI data in hold from SPI CLK in falling	60		ns	1,2	
SP20	SPI CLK in falling to SPI data out valid	20	70	ns	0,3	6
SP21	SPI CLK in rising to SPI data out valid	20	70	ns	1,2	6

Parm	Description	Min	Max	Unit	Mod es	Not es
SP22	SPI enable low hold from last SPI CLK in falling	15		ns	0,3	1
SP23	SPI enable low hold from last SPI CLK in rising	15		ns	1,2	1
SP24	SPI CLK in high time	SP26*40%	SP26*60%	ns	0,1,2,3	5
SP25	SPI CLK in low time	SP26*40%	SP26*60%	ns	0,1,2,3	5
SP26	SPI CLK in period	$T_{BCLK} * 8$		ns	0,1,2,3	3

Notes:

- 1 Active level of SPI enable is inverted (that is, 1) if the CSPOL bit in Serial Channel Control Register B is set to a 1. Note that in SPI slave mode, only a value of 0 (low enable) is valid; the SPI slave is fixed to an active low chip select.
- 2 SPI data order is reversed (that is, LSB last and MSB first) if the BITORDR bit in Serial Channel Control Register B is set to a 0.
- 3  $T_{BCLK}$  is period of AHB clock.
- 4  $\pm 5\%$  duty cycle skew.
- 5  $\pm 10\%$  duty cycle skew.
- 6  $C_{load} = 5\text{pf}$  for all outputs.
- 7 SPI data order can be reversed such that LSB is first. Use the BITORDR bit in Serial Channel B/A/C/D Control Register A.

### SPI master mode 0 and 1: 2-byte transfer

Note: SPI data can be reversed such that LSB is first. Use the BITORDER bit in Serial Channel B/A/C/D Control Register A.

### SPI master mode2 and 3: 2-byte transfer

Note: SPI data can be reversed such that LSB is first. Use the BITORDER bit in Serial Channel B/A/C/D Control Register A.

### SPI slave mode 0 and 1: 2-byte transfer

Note: SPI data can be reversed such that LSB is first. Use the BITORDER bit in Serial Channel B/A/C/D Control Register A.

### SPI slave mode 2 and 3: 2-byte transfer

Note: SPI data can be reversed such that LSB is first. Use the BITORDER bit in Serial Channel B/A/C/D Control Register A.

# Reset and hardware strapping timing

Parm	Description	Min	Typ	Unit	Notes
R1	reset_n minimum time	10		x1_sys_osc clock cycles	1, 2
R2	reset_n to reset_done		NOR flash: 0.2 SPI flash: 10.5	ms	

Notes:

- 1 The hardware strapping pins are latched 5 clock cycles after reset\_n is deasserted (goes high).
- 2 From a cold start the x1\_sys\_osc clock source may require up to 10ms before oscillation starts.

## JTAG timing

All AC characteristics are measured with 10pF, unless otherwise noted.

The next table describes the values shown in the JTAG timing diagram.

Parm	Description	Min	Max	Unit
J1	tms (input) setup to tck rising	5		ns
J2	tms (input) hold to tck rising	2		ns
J3	tdi (input) setup to tck rising	5		ns
J4	tdi (input) hold to tck rising	2		ns
J5	tdo (output) to tck falling	2.5	10	ns

### Notes:

- 1 Maximum tck rate is 10 MHz.
- 2 rtck\_out is an asynchronous output, driven off of the CPU clock.
- 3 trst\_n is an asynchronous input.

# Clock timing

All AC characteristics are measured with 10pF, unless otherwise noted.

## System PLL reference clock timing

Parm	Description	Min	Max	Unit	Notes
SC1	x1_sys_osc cycle time	25	50	ns	
SC2	x1_sys_osc high time	$(SC1/2) \times 0.45$	$(SC1/2) \times 0.55$	ns	
SC3	x1_sys_osc low time	$(SC1/2) \times 0.45$	$(SC1/2) \times 0.55$	ns	

The diagram below pertains to clock timing.

# Packaging

## C H A P T E R 1 7

**B**elow is the processor package, 265 LF-XBGA. Diagrams that follow show the processor dimensions: top, bottom, and side views.

### Package

# Processor Dimensions

# Change Log

## C H A P T E R 1 8

The following changes were made since the last revision of this document.

### Revision B

- 1 Modified ADC data in the POR table.
- 2 Added RTC clock and battery backup connection information.
- 3 Updated POR and battery backup logic information for situations when the POR feature is not used.
- 4 Added power dissipation data for 75MHz.
- 5 Deleted IDDS because it does not apply to this type of IC.

### Revision C

- 1 Added flexible interface Module signals to include PIC signals with GPIO pin out signals table.

### Revision D

- 1 Extensive corrections were made throughout the document.

### Revision E

- 1 Added a note after the Features section at the beginning of the AES Data Encryption/Decryption chapter.

### Revision F

- 1 Changed "When set bits 04:03=00" to "When set bits 04:03=01" in the Register Bit Assignment Table.

- 
- 2 Changed function 1 of GPIO[74] to PIC\_1\_GEN\_IO[6] instead of PIC\_0\_GEN\_IO[6], on page 39.
  - 3 Changed the description for mode 1 of gpio[14] from "DMA Req Ch 1" to "Ext DMA Req Ch 1" on page 33.
  - 4 In the data blocks table, changed "Throughput @ 75 MHZ" units from bytes per second to MegaBytes per second.

## Revision G

- 1 Removed the line "the processor I/O are 5 volt tolerant" from the DC electrical characteristics Inputs section of chapter 16.

## Revision H

- 1 Re-added the line "the processor I/O are 5 volt tolerant" to the DC electrical characteristics Inputs section of chapter 16.
